**Re: Northwest Ohio Wind Energy, LLC
OPSB Case No. 13-197-EL-BGN**

Dear Ms. McCauly:

On May 28, 2013, Northwest Ohio Wind Energy, LLC ("Northwest") filed an Application with the Ohio Power Siting Board for a Certificate of Environmental Compatibility and Public Need under Ohio Administrative Code Chapter 4906-17. The purpose of this letter is to submit for late filing Appendix I, Noise Impact Study. As Staff is aware, Northwest has been waiting for this study, which has just been received.

Also attached is a new application narrative for Section 4906-17-08 Social and Ecological Data, (A) Health and Safety (2) Noise, which has been updated to reflect the noise study of Appendix I. The attached pages replace the application narrative beginning the bottom of page 66 through page 74 of the application.

Please do not hesitate to contact me if you have any questions.

Sincerely,

Sally W. Bloomfield

1. INTRODUCTION

The Northwest Ohio Wind Project, a proposed National Wind development, is an approximately 100 MW wind power project to be located in Paulding County, Ohio. RSG was hired to perform a noise impact assessment consistent with OPSB precedents set for similar projects. Included in this report are:

- A project description,
- A primer on the science of sound,
- An overview of standards and precedents that apply to the project,
- Background sound level monitoring results,
- A discussion of noise issues particular to wind turbines,
- Sound propagation modeling results,
- Construction impact modeling results, and
- Conclusions

2. PROJECT DESCRIPTION

The proposed Northwest Ohio Wind Project will be located in Paulding County, Ohio. There will be up to 59 turbines located northwest of Grover Hill, north of Ohio 114, south of Ohio 613, and east of Payne. US 127 runs north to south down the center of the project area. The project area is adjacent to Iberdrola Renewables' Blue Creek Wind Farm which is located south of Ohio 114. A map of the proposed site is shown in Figure 1 and a map of the area including turbines from the Blue Creek Wind Farm is shown in Figure 2.

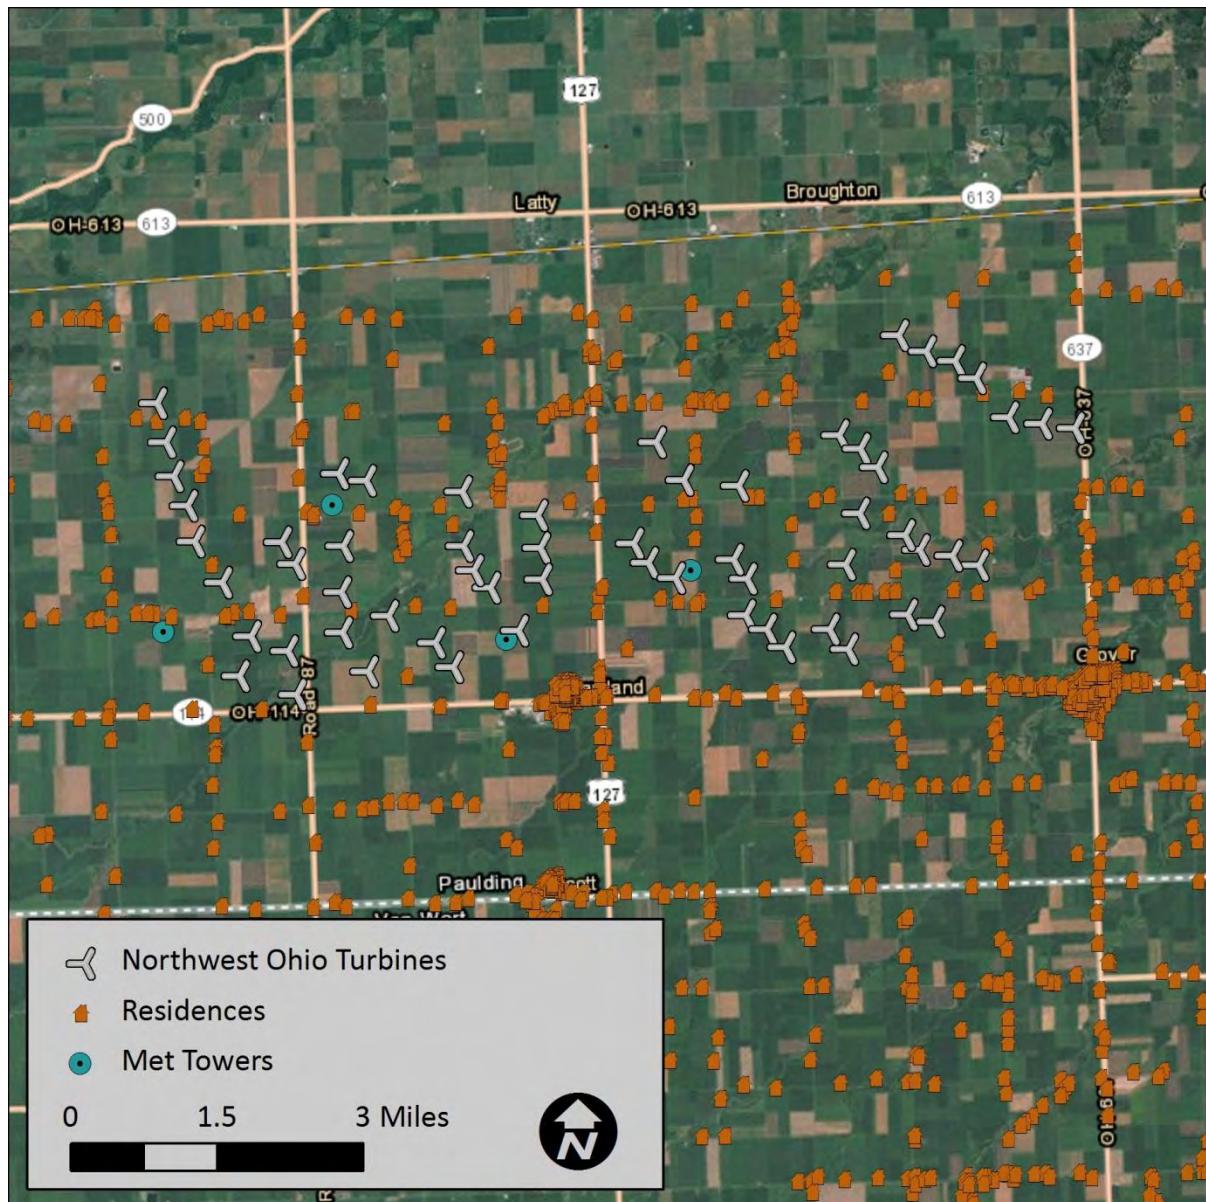

Figure 1: Project Site Map

Figure 2: Area Map with Proposed Northwest Ohio Turbines & Existing Blue Creek Turbines

3. NOISE PRIMER

3.1 How is Sound Described?

Sound is caused by variations in air pressure at a range of frequencies. Sound levels that are detectable by human hearing are defined in the decibel (dB) scale, with 0 dB being the approximate

threshold of human hearing, and 135 dB causing pain and permanent damage to the ear. Figure 3 shows the sound levels of typical activities that generate noise.

The decibel scale can be weighted to mimic the human perception of certain frequencies. The most common of these weighting scales is the “A” weighting. It is used most frequently in environmental noise analyses. Sound levels that are weighted by the “A” scale have units of dBA or dB(A).

3.2 What is the Difference between Sound Pressure Levels and Sound Power Levels?

Both sound power and sound pressure levels are described in terms of decibels, but they are not the same thing. Sound power is a measure of the acoustic power emitted or radiated by a source. The sound power level of a source does not change with its surrounding conditions.

Sound pressure level is observed at a specific location and is related to the difference in air pressure above or below atmospheric pressure. This fluctuation in air pressure is a result of the sound power of a source, the distance at which the sound pressure level is being observed, and the characteristics of the path and environment around the source and receiver. When one refers to sound level, they are generally speaking of the perceived level, or sound pressure level.

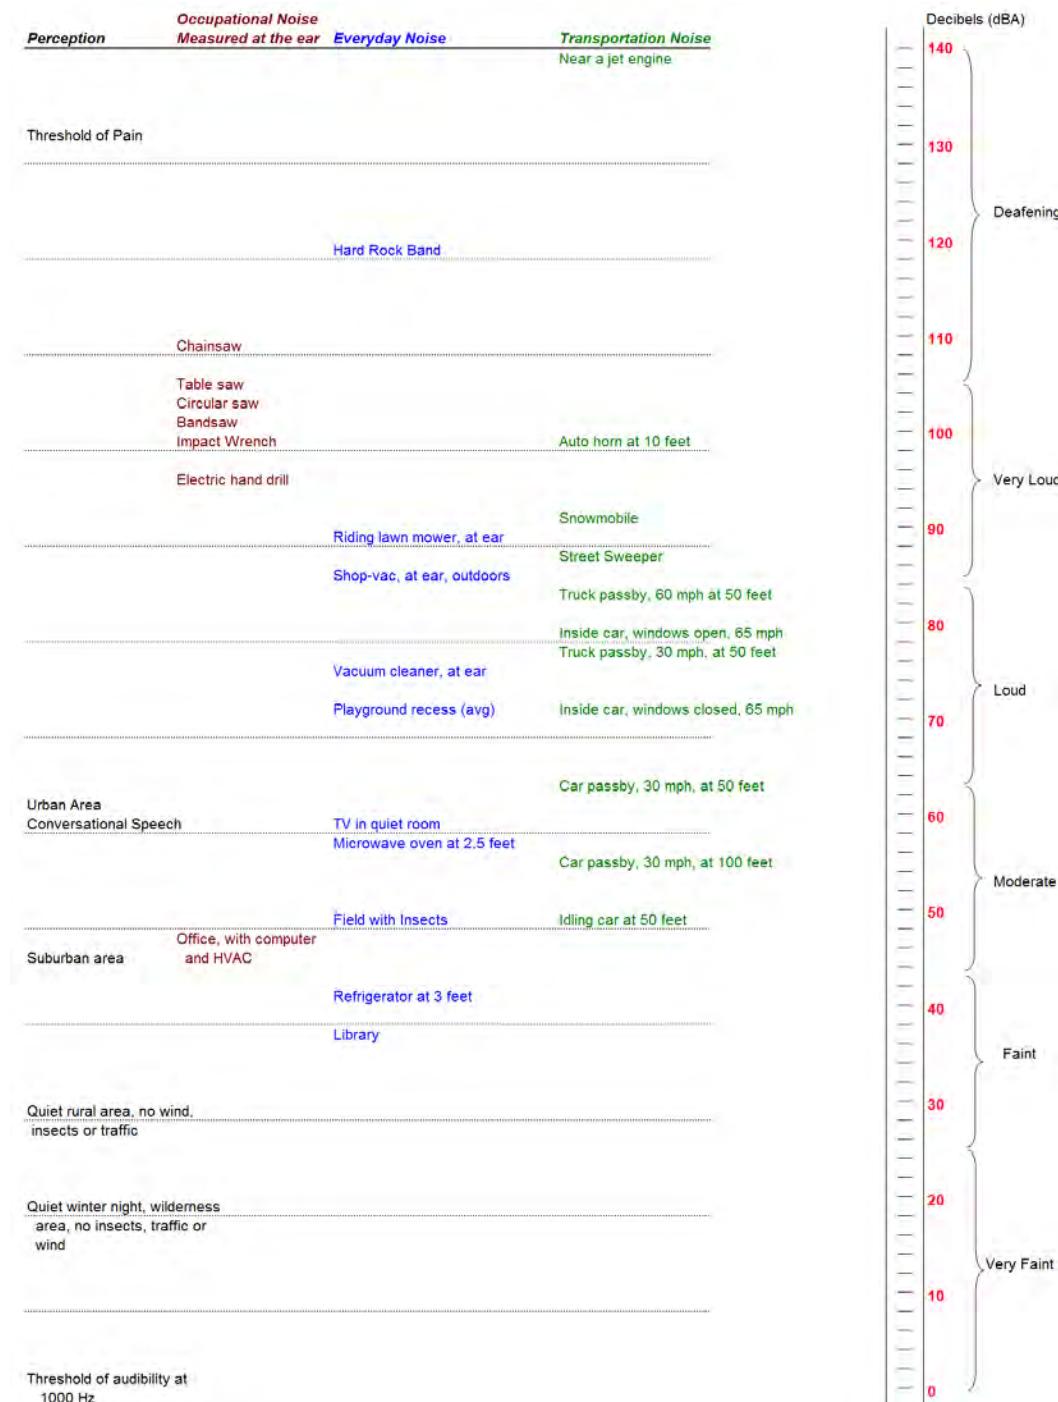

For example, a coffee grinder will have the same sound power whether or not it is grinding indoors or outdoors. The amount of sound the coffee grinder generates is always the same. However, if you are standing six meters away from the coffee grinder indoors, you would experience a higher sound pressure level than you would if you were six meters away from the coffee grinder outdoors in an open field. The reason for this is that the sound being emitted from the coffee grinder would bounce off walls and other surfaces indoors which would cause sound to build up and raise the sound pressure level.

Sound power cannot be directly measured. However, since sound pressure and sound power are related, sound power can be calculated by measurements of sound pressure and sound intensity. It can be helpful to note that over soft ground outside, the sound pressure level of a small source observed 50 meters away is roughly 33 dB lower than its sound power level.

3.3 How is Sound Modeled?

The decibel sound level is described on a logarithmic scale. One manifestation of this is that sound power increases by a factor of 10 for every 10 dB increase. However, for every 10 dB increase in sound pressure, we perceive an approximate doubling of loudness. Small changes in sound level, below 3 dB, are generally not perceptible.

**Figure 3: Common Sounds in A-weighted Decibels¹**

¹ Background hourly equivalent average sound levels in rural areas with windy conditions such as Paulding County typically range from 35 to 50 dBA which is dependent on wind speed and vegetation.

For a point source, sound level diminishes or attenuates by 6 dB for every doubling of distance due to geometrical divergence. For example, if an idling truck is measured at 50 meters as 66 dBA, at 100 meters the level will decline to 60 dBA, and at 200 meters, 54 dBA, assuming no other influences. From a line source, like a gas pipeline or from closely spaced point sources, like a roadway or string of wind turbines, sound attenuates at approximately 3 dB per of doubling distance. These “line sources” transition to an attenuation of 6 dB per doubling at a distance of roughly a third of the length of the line source. Wind turbines are best approximated as point sources, at distances greater than the length of the blades.

Other factors, such as intervening vegetation, terrain, walls, berms, buildings, and atmospheric absorption will also further reduce the sound level reaching the listener. In each of these, higher frequencies will attenuate faster than lower frequencies. Finally, the ground can also have an impact on sound levels. Harder ground generally increases and softer ground generally decreases the sound level at a receiver. Reflections off of buildings and walls can increase broadband sound levels by as much as 3 dB.

If we add two equal sources together, the resulting sound level will be 3 dB higher. For example, if one machine registers 76 dBA at 50 meters, two co-located machines would register 3 dB more, or 79 dBA at that distance. In a similar manner, at a distance of 50 meters, four machines, all operating at the same place and time, would register 82 dBA and eight machines would register 85 dBA. If the two sources differ in sound level then 0 to 3 dB will be added to the higher level as shown in Table 1.

Table 1: Decibel Addition

If Two Sources Differ By	Add
0-1 dB	3 dB
2-4 dB	2 dB
5-9 dB	1 dB
>9 dB	0 dB

Subtracting sound levels follow the same principles as addition. If there are two co-located machines of equal sound power level and one is turned off, sound levels will decrease by 3 dB. Similarly, if there are two co-located machines that differ in sound power level by between 5 and 9 dB, and the quieter machine is turned off, the overall sound level will decrease by 1 dB.

3.4 Description of Terms

Sound can be measured in many different ways. Perhaps the simplest way is to take an instantaneous measurement, which gives the sound pressure level at an exact moment in time. The level reading could be 62 dB, but a second later it could 57 dB. Sound pressure levels are constantly changing. It is for this reason that it makes sense to describe noise and sound in terms of time.

The most common ways of describing noise over time is in terms of various levels. Take as an example, the sound levels measured over time shown in Figure 4. Instantaneous measurements are shown as a ragged grey line. The sound levels that occur over this time can be described verbally, but it is much easier to describe the recorded levels statistically. This is done using a variety of “levels” which are described below.

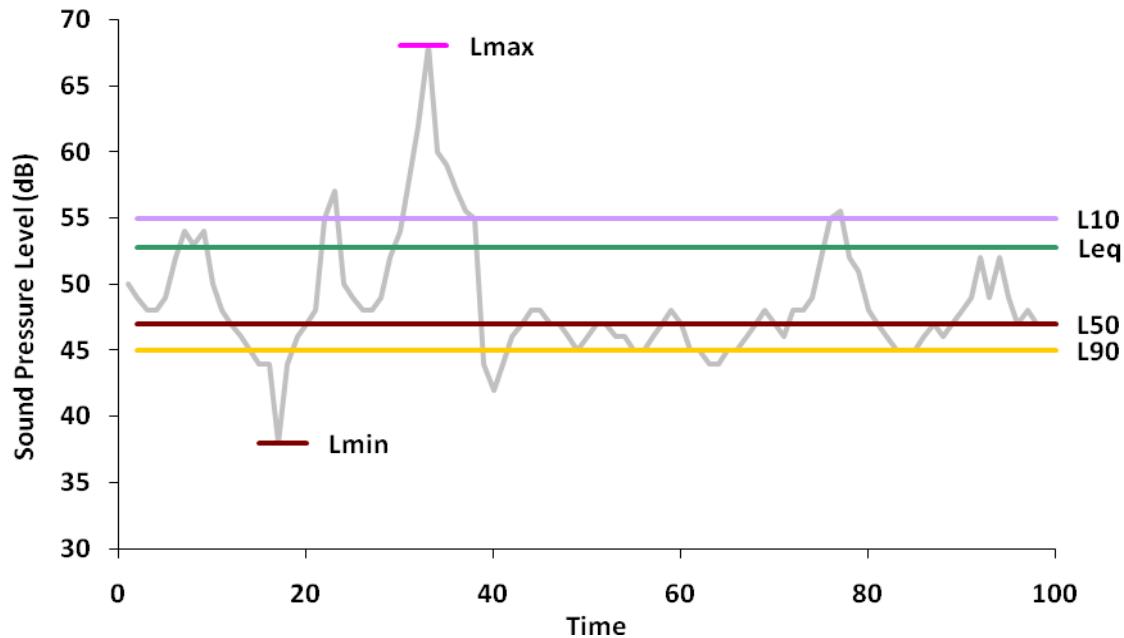

Figure 4: Example of Descriptive Terms of Sound Measurement over Time

3.4.1 Equivalent Average Sound Level - Leq

One of the most common ways of describing noise levels is in terms of the continuous equivalent sound level (Leq). The Leq is the average of the sound pressure over an entire monitoring period and expressed as a decibel. The monitoring period could be for any amount of time. It could be one second ($Leq_{1\text{-sec}}$), one hour ($Leq_{(1)}$), or 24 hours ($Leq_{(24)}$). Because Leq describes the average pressure, loud and infrequent noises have a greater effect on the resulting level than quieter and more frequent noises. For example, in Figure 4, the median sound level is about 47 dBA, but the equivalent average sound level (Leq) is 53 dBA. Because it tends to weight the higher sound levels and is representative of sound that takes place over time, the Leq is the most commonly used descriptor in noise standards and regulations.

3.4.2 Percentile Sound Level - L_n

L_n is the sound level exceeded n percent of the time. This type of statistical sound level, also shown in Figure 4, gives us information about the distribution of sound levels over time. For example, the

L10 is the sound level that is exceeded 10 percent of the time, while the L90 is the sound level exceeded 90% of the time. The L50 is exceeded half the time.

3.4.3 Lmin and Lmax

Lmin and Lmax are simply the minimum and maximum sound level, respectively, monitored over a period of time.

4. NOISE STANDARDS

There are no state statutes or regulations that establish quantitative noise standards which are applicable to this project.

There are precedents set by the Ohio Power Siting Board (OPSB) for other wind power projects within the state. Recently, in the Buckeye II Wind Farm project, the OPSB placed the following condition:

“The facility shall be operated so that the facility noise contribution does not result in noise levels at the exterior of any currently existing nonparticipating sensitive receptor that exceed the project area ambient nighttime Leq of 39 dBA, plus five dBA. During daytime operations only, 7:00 a.m. to 10:00 p.m., the facility may operate at the greater of: (a) the project area ambient nighttime Leq, 39 dBA, plus five dBA; or (b) the validly measured ambient (Leq), plus five dBA, at the location of the sensitive receptor.”

This condition for the Buckeye II Wind Farm set the applicable nighttime noise limit for the development to 5 dBA above the facility area nighttime ambient noise levels (Leq) and the same limit is used for daytime operations unless a greater ambient noise levels (Leq) at the location of the sensitive receptor is known, in which case the daytime limit would be the greater ambient noise level (Leq) at the sensitive receptor location, plus 5 dBA.

Based on ambient sound monitoring done at five locations around the project area (Section 5), the average nighttime (Leq_{night}) is 43 dBA. The nighttime limit for this project would be 48 dBA under the Buckeye II project precedent. This limit also applies to the daytime except in instances where the daytime ambient noise level (Leq) is higher than 43 dBA at a sensitive receptor. Based on ambient sound monitoring at the five locations around the project area (Section 5), the daytime ambient level ranged from 39 to 59 across the five monitoring locations. The daytime limit for the project would be between 48 dBA (the nighttime limit) and 64 dBA (highest daytime ambient plus 5 dBA) depending on the sensitive receptor.

Although prior board precedent would allow a project limit of 48 dBA, the project will use a design goal of 45 dBA for nighttime operations. This is based on World Health Organization (WHO) guidelines. In their “Guidelines for Community Noise” (1999), the WHO reviewed the most current research on the health impacts of noise to develop guideline sound levels for communities. To quote the foreword of the report, “The scope of WHO’s effort to derive guidelines for community

noise is to consolidate actual scientific knowledge on the health impacts of community noise and to provide guidance to environmental health authorities and professionals trying to protect people from the harmful effect of noise in non-industrial environments.” The WHO concluded that the sound level averaged over the eight nighttime hours should not exceed 45 dBA, (also indicated as 45 dBA Leq₍₈₎), to protect against health impacts, specifically sleep disturbance, due to noise.

In cases where existing sound levels at sensitive receptors exceed these limit, primarily along OH 114, the Northwest Ohio Wind Project will not cause increases in modeled sound levels at those locations that are greater than 1 dB.

5. BACKGROUND SOUND LEVEL MONITORING

5.1 Methodology

Long term sound level monitoring was conducted at five locations (Figure 5) in the project area from May 24, 2013 until May 31, 2013. Temperatures during the monitoring period ranged 41° to 86° F, and average one-minute wind speeds (5 foot height) ranged from 0 to 21 mph with gusts as high as 26 mph. Most of the periods of higher winds occurred on May 28, 29, and 30. There were some light rainy periods on May 27 (6:30 a.m. to 10:00 a.m. & 1 p.m. to 6 p.m.) and May 28 (4:30 a.m. to 6:30 a.m.).

Sound level data was collected using either ANSI/IEC Type 2 Rion NL-22 sound level meters or ANSI/IEC Type 1 Cesva SC310 sound level meters. The Rions were set to log 1 second equivalent A-weighted sound levels every one-second and the Cesvas were set to log 1/3 octave band sound levels every one-second. The Rions were set to record audio clips of sound events that exceeded 55 dBA and the Cesvas were connected to Roland R-05 or R-09 HR sound recorders. The microphones were mounted on a 1.5 meter (5 foot) tall wooden stakes and covered with a 7 inch ACO-Pacific weather resistant windscreens.

Data was summarized into 10-minute periods. All periods that contained precipitation and sustained wind speeds above 11 mph were eliminated during post-processing.

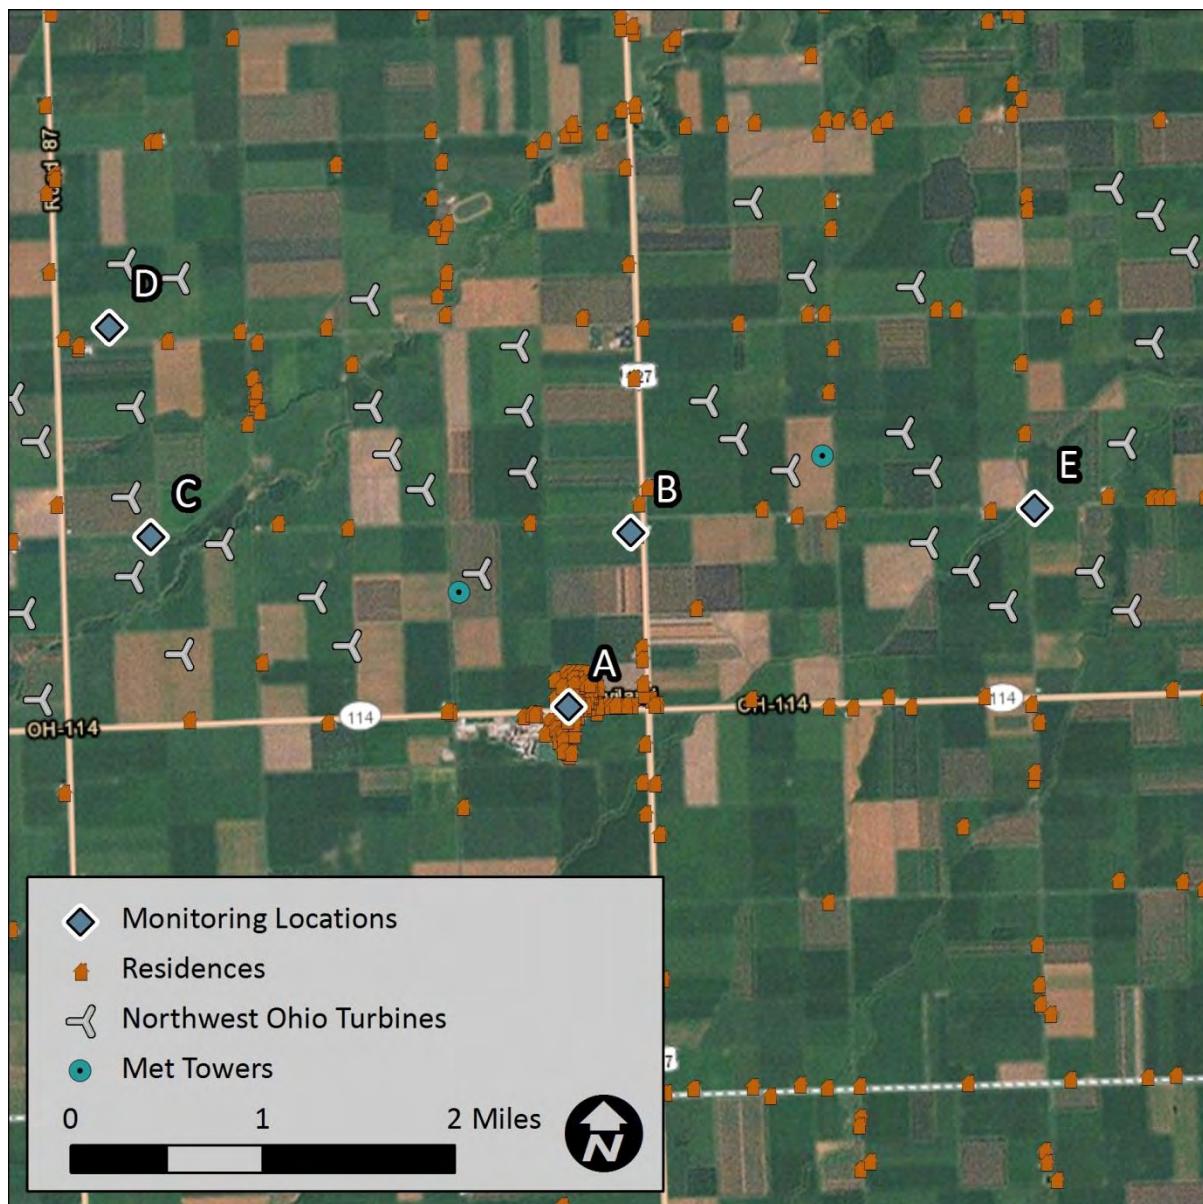

Figure 5: Map of Background Monitoring Locations

5.2 Monitoring Results Summary

A summary of the monitoring results is shown in Table 2. In all cases the nighttime Leq levels are less than daytime Leq levels, which is typical. There is also a generally large spread between the Leq and L90 values, indicating that the soundscapes at most sites are dominated by intermittent sounds (such as car passbys and airplane overflights) instead of constant sound sources (such as streams and distant traffic).

To determine the sound level limit for the project, 5 dB was added to the average nighttime Leq, resulting in a sound level limit of 48 dBA.

Table 2: Monitoring Summary

Location	Sound Pressure Level (dBA)											
	Overall				Day				Night			
	Leq	L90	L50	L10	Leq	L90	L50	L10	Leq	L90	L50	L10
A	56	37	46	54	59	40	47	55	51	34	45	53
B	46	27	37	48	46	29	39	49	45	26	37	48

E	44	24	33	43	44	23	34	45	43	24	33	42
Noise Standard	Average Nighttime Leq 43 dBA				Average Nighttime Leq + 5 dB 48 dBA							

5.3 Monitoring Results by Site

5.3.1 Monitor A

Monitor A was located in Haviland in a lot on the northwest corner of OH 114 (Main Street) and McKinley Street. The meter was set back approximately 100 feet from the centerline of OH 114 and 60 feet from the centerline of McKinley Street. Figure 6 and Figure 7 show a map and a photograph of the monitoring location, respectively.

Time-history results for Monitor A are shown in Figure 8. The sound levels at Monitor A are the highest of the five monitoring locations, which is to be expected at an in-town location with a state highway that runs through it. The sound levels are diurnal, decreasing at night, with the difference between the Leq and L90 also decreasing at night. Major sound sources at the site included vehicle passbys, birds, and anthropogenic sounds that are typical of a small town.

Figure 6: Monitor A Map

Figure 7: Photograph of Monitor A

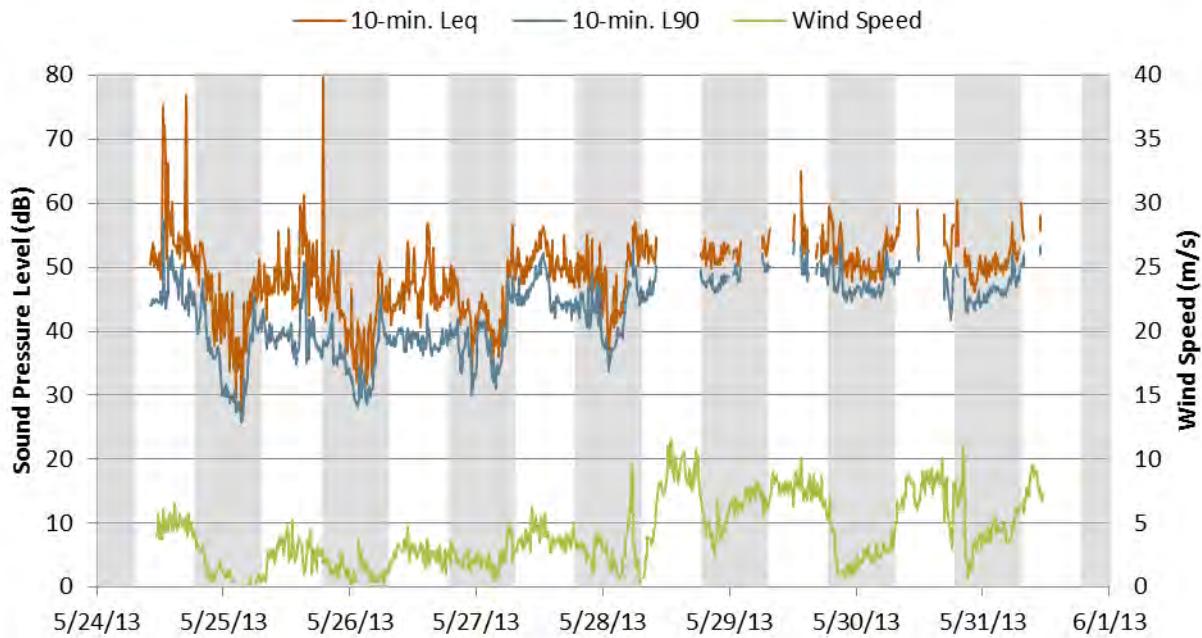

Figure 8: Monitor A Time History Results

5.3.2 Monitor B

Monitor B was located at a residence north of Haviland in the middle of the project area on US 127. The meter was located approximately 160 feet west of the residence, 100 feet north of a farm outbuilding, and approximately 25 feet north of a small shed. It was set back approximately 340 feet west of the US 127 centerline and 475 feet south of Town Highway 48. Figure 9 and Figure 10 show a map and a photograph of the monitoring location, respectively.

Time-history results for are shown in Figure 11. Results show a diurnal pattern with a generally large spread between the Leq and L90, indicated that most major sound sources were short duration sounds (e.g. vehicle passbys). The main sources of sound at the monitor were vehicle passbys, birds, airplane overflights, and mechanical sounds from farm operations.

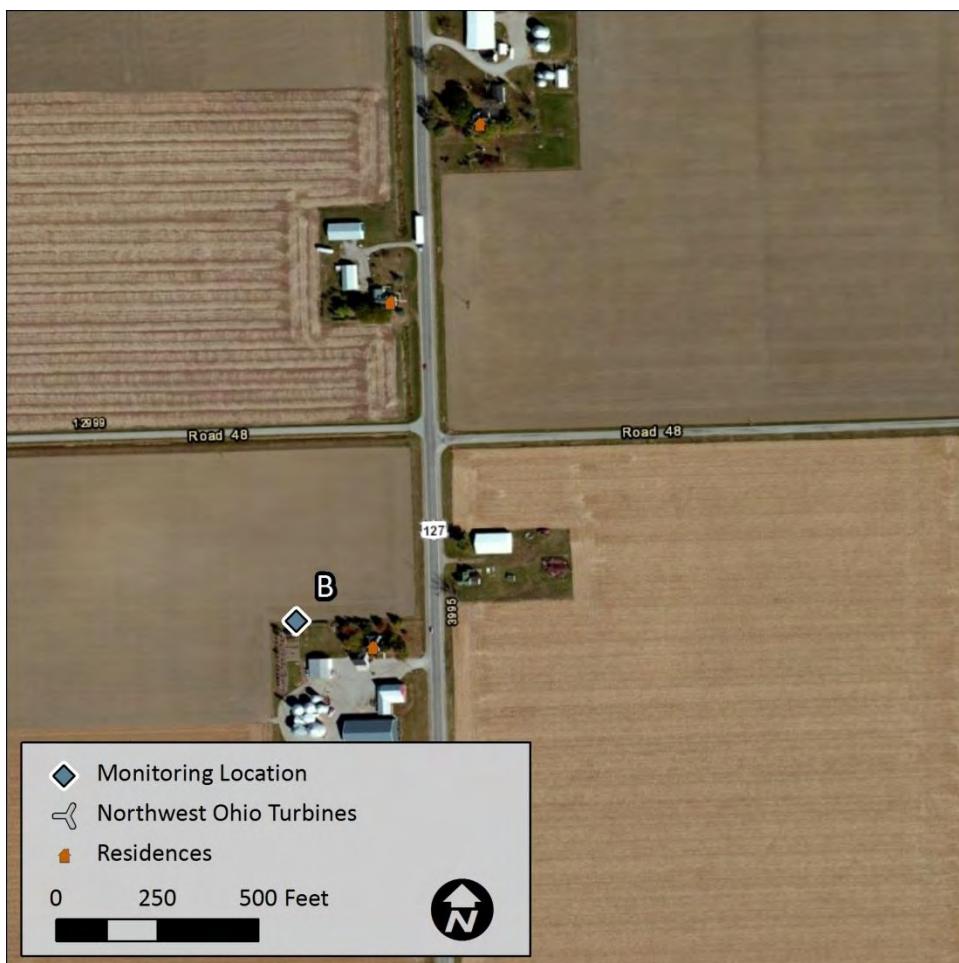

Figure 9: Monitor B Map

Figure 10: Photograph of Monitor B

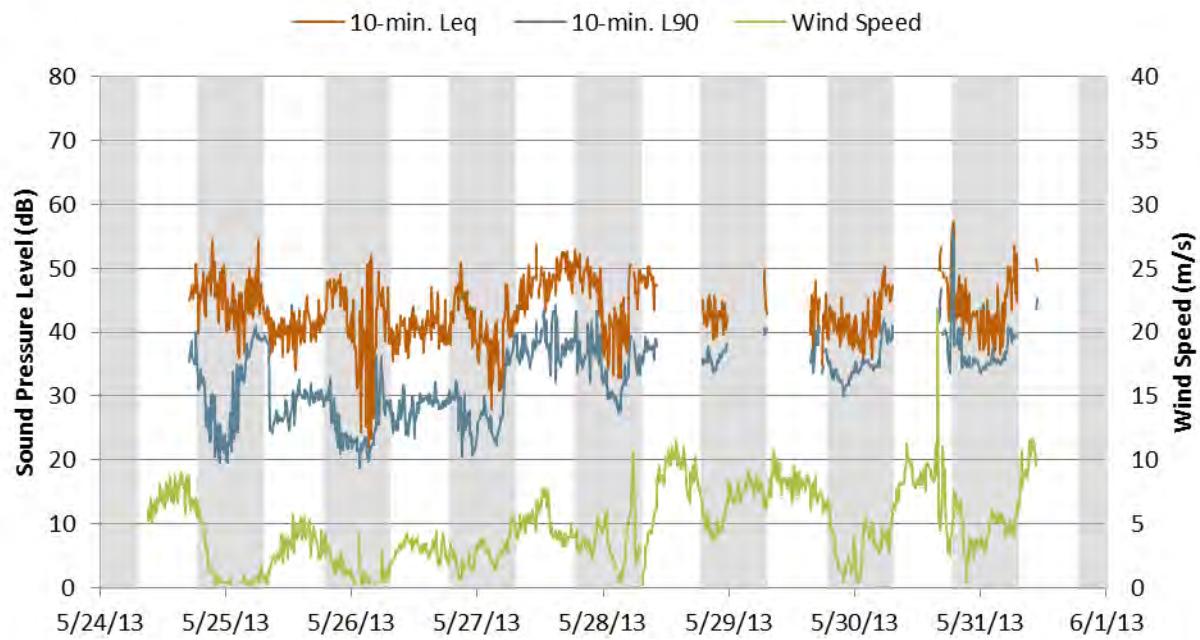

Figure 11: Monitor B Time History Results

5.3.3 Monitor C

Monitor C was located at a residence on the western edge of the project away from major roadways. The meter was located approximately 65 feet southwest of the residence near a pine tree, and was set back approximately 150 feet south of the Town Highway 48 centerline. Figure 12 and Figure 13 show a map and a photograph of the monitoring location, respectively.

Time-history results are shown in Figure 14. The sound levels at Monitor C are diurnal. Major sound sources at the site included birds, airplane overflights, wind induced foliage sound, and occasional mechanical sounds from farm operations.

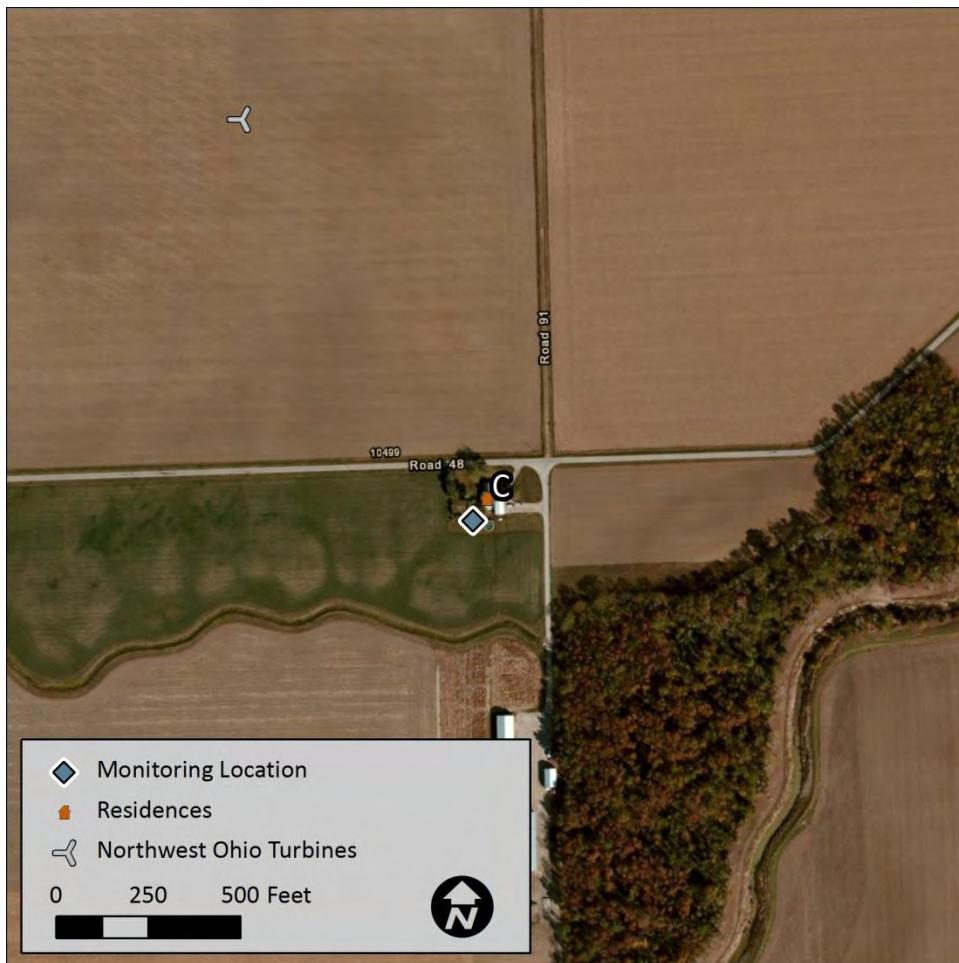

Figure 12: Monitor C Map

Figure 13: Photograph of Monitor C

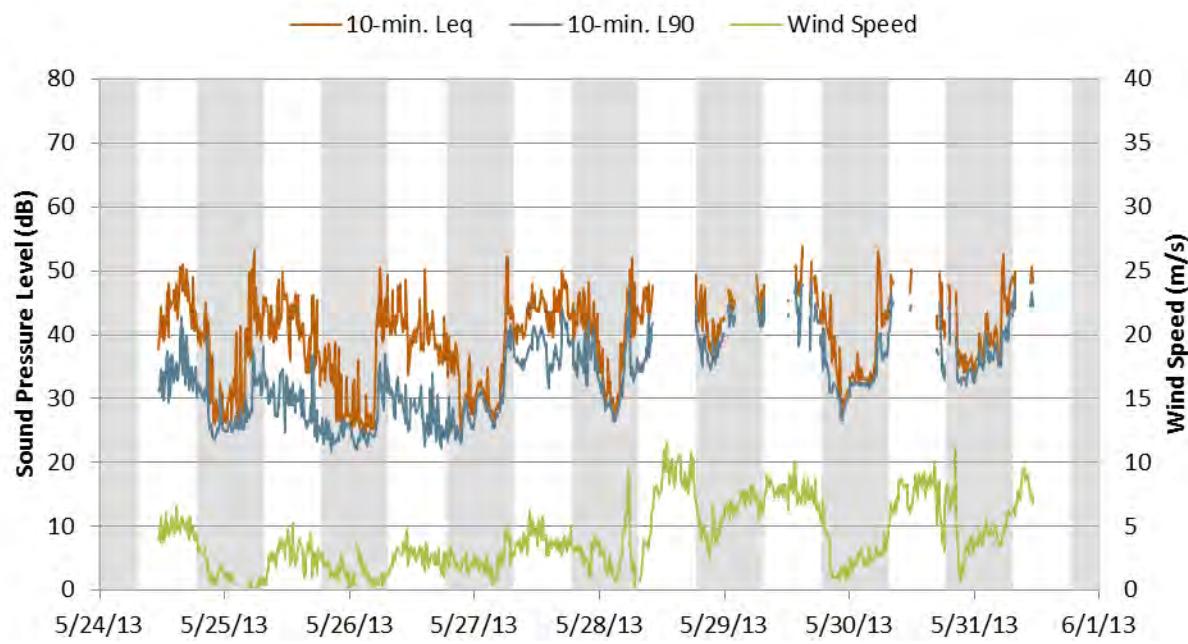

Figure 14: Monitor C Time History Results

5.3.4 Monitor D

Monitor D was located in a field in the northwestern corner of the project area away from major roadways. The meter was located approximately at a residence on the western edge of the project away from major roadways. The meter was located approximately 165 feet west of a project meteorological tower, 1,460 feet east of Town Highway 87, and 340 feet north of Town Highway 60. Figure 15 and Figure 16 show a map and a photograph of the monitoring location, respectively.

Time-history results are shown in Figure 17. The sound levels at Monitor D are the lowest of the five monitoring locations and less diurnal than the other sites, partly due to the monitor not being located at a residential area. The nearest residence to Monitor D is 960 feet to the west-southwest. The major sound sources at the site are birds, airplane overflights, and occasional mechanical equipment in the distance.

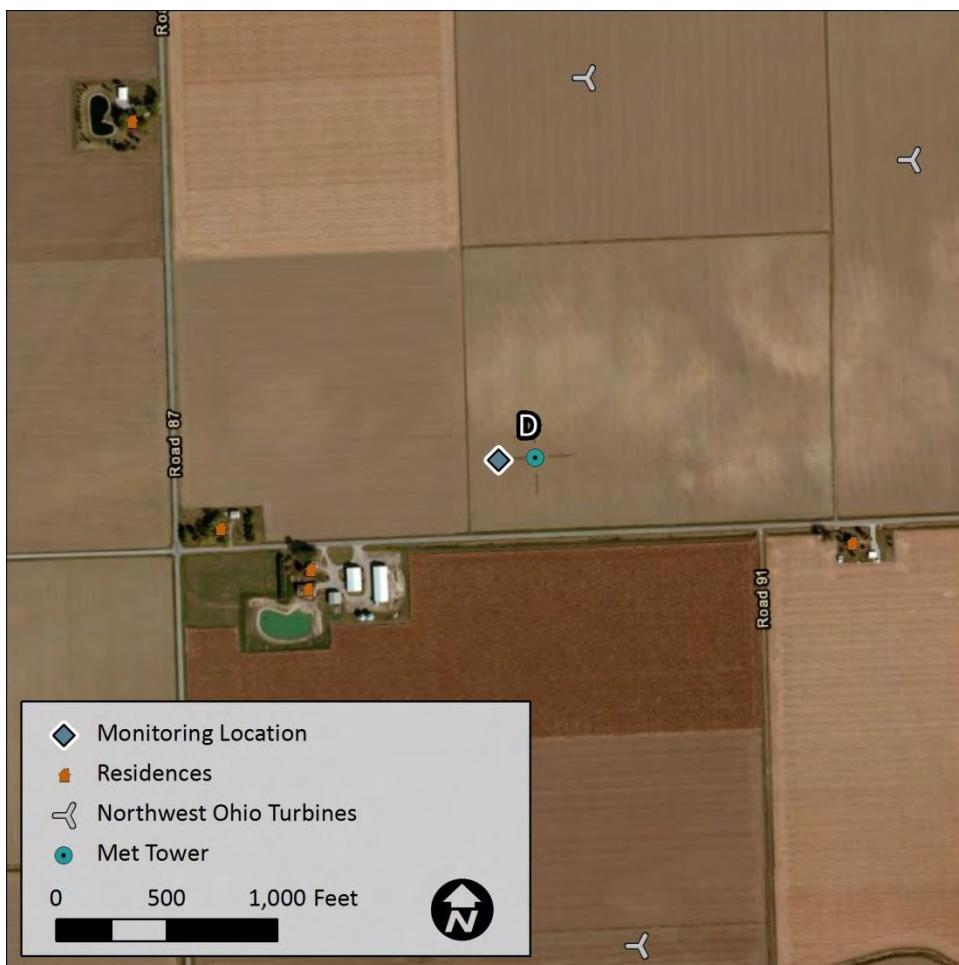

Figure 15: Monitor D Map

Figure 16: Photograph of Monitor D

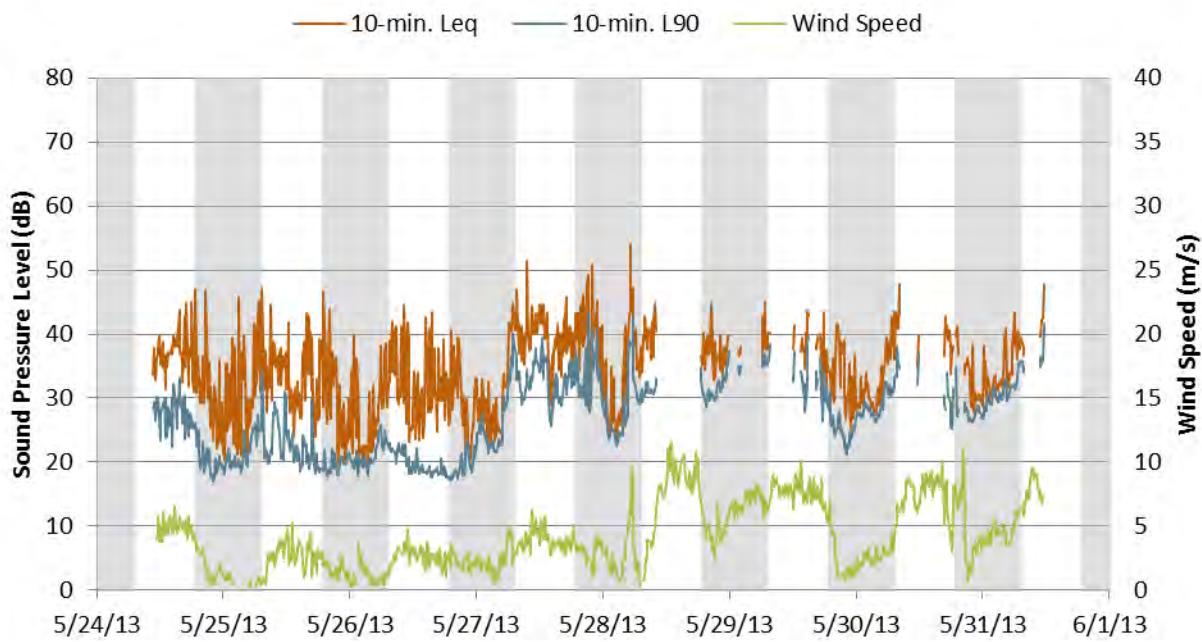

Figure 17: Monitor D Time History Results

5.3.5 Monitor E

Monitor E was located near farm building on the eastern end of the project area away from major roadways. The meter was located approximately 70 feet west of the farm building, 95 feet south of Town Highway 48, and 135 feet east of Town Highway 123. Figure 18 and Figure 19 show a map and a photograph of the monitoring location, respectively.

Time-history results are shown in Figure 20. The sound levels at Monitor E are slightly diurnal, partly due to the monitor not being located at a residential area. The nearest residence to Monitor D is 1,200 feet to the west. The major sound sources at the site include birds, airplane overflights, occasional mechanical equipment, and vehicle passbys.

Figure 18: Monitor E Map

Figure 19: Photograph of Monitor E

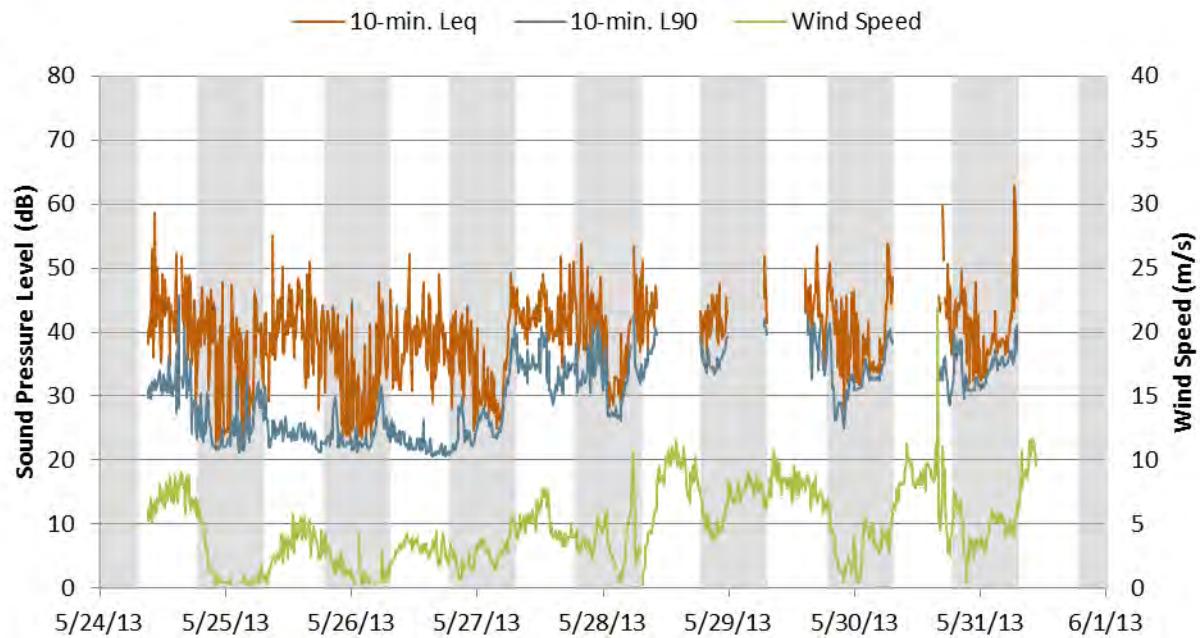

Figure 20: Monitor E Time History Results

6. SOUND LEVELS PRODUCED BY WIND TURBINES

6.1 Standards Used to Measure Wind Turbine Sound Emissions

A manufacturer of a wind turbine must test and report sound emissions from its turbines using two international standards:

1. International Electrotechnical Commission standard IEC 61400-11:2002(E), "Wind Turbine Generator Systems – Part 11: Acoustic Noise Measurement Techniques"
2. International Electrotechnical Commission standard IEC 61400-14:2005(E), "Wind Turbine Generator Systems – Part 14: Declaration of Apparent Sound Power Level and Tonality Values"

These standards provide sound power emission levels from a turbine, by wind speed and frequency. They also provide a confidence interval.

6.2 Manufacturer Sound Emissions Estimates

Since a specific turbine has not yet been chosen for this project, three turbines have been considered: the Gamesa G114 with a 93 meter hub height, the Vestas V110 with a 95 meter hub height, and the General Electric GE 1.7-100 with a hub height of 96 meters.

Sound emissions from a wind turbine are measured as *sound power*. This is different from the *sound pressure* that one measures on a sound level meter. Sound power is the acoustical energy emitted by an object, and sound pressure is the measured change in pressure caused by acoustic waves at an observer location.

The sound power level of the GE 1.7-100 is 107 ± 2 dBA for wind speeds of 7 m/s and greater (10-meter anemometer height). The estimated sound power level of the Gamesa G114 is 106 ± 2 dBA for wind speeds of 6 m/s and greater (10-meter anemometer height), and the estimated sound power level of the Vestas V110 is 107.5 ± 2 dBA. The modeled levels for this study account for the upper end of the sound power uncertainties, so that the GE, Gamesa, and Vestas turbines are modeled at 109, 108, and 109.5 dBA respectively. The octave band sound power levels used in this study's model are shown in Table 3.

Table 3: Turbine Sound Power Levels (dBA)

Wind Turbine Model	Maximum Sound Power Level including Uncertainty	Octave Band Center Frequency								
		31.5 Hz	63 Hz	125 Hz	250 Hz	500 Hz	1000 Hz	2000 Hz	4000 Hz	8000 Hz
Gamesa G114	108.0	71	81	90	97	101	100	98	95	87
GE 1.7-100	109.0	81	90	95	98	102	102	98	91	72
Vesta V110	109.5	81	88	94	98	101	102	101	97	85
Gamesa G90 (Blue Creek)	108.8		84	93	100	102	100	97	95	91

7. SOUND FROM WIND TURBINES – SPECIAL ISSUES

7.1 Wind Turbine Noise

Wind turbines generate two principle types of noise: aerodynamic noise, produced from the flow of air around the blades, and mechanical noise, produced from mechanical and electrical components within the nacelle.

Aerodynamic noise is the primary source of noise associated with wind turbines. These acoustic emissions can be either tonal or broadband. Tonal noise occurs at discrete frequencies, whereas broadband noise is distributed with little peaking across the frequency spectrum.

While unusual, tonal noise can also originate from unstable air flows over holes, slits, or blunt trailing edges on blades. Most modern wind turbines have upwind rotors designed to prevent blade impulsive noise. Therefore, the majority of audible aerodynamic noise from wind turbines is broadband at the middle frequencies, roughly between 200 Hz and 1,000 Hz.

Wind turbines emit aerodynamic broadband noise as the spinning blades interact with atmospheric turbulence and as air flows along their surfaces. This produces a characteristic “whooshing” sound through several mechanisms (Figure 21):

- *Inflow turbulence noise* occurs when the rotor blades encounter atmospheric turbulence as they pass through the air. Uneven pressure on a rotor blade causes variations in the local angle of attack, which affects the lift and drag forces to cause aerodynamic loading fluctuations. This generates noise that varies across a wide range of frequencies but is most significant at levels below 500 Hz.
- *Trailing edge noise* is produced as boundary-layer turbulence around the airfoil passes into the wake, or trailing edge, of the blade. This noise is distributed across a wide frequency range but is most notable at high frequencies between 700 Hz and 2 kHz.
- *Tip vortex noise* occurs when tip turbulence interacts with the surface of the blade tip. While this is audible near the turbine, it tends to be a small component of the overall noise further away.
- *Stall or separation noise* occurs due to the interaction of turbulence with the blade surface.

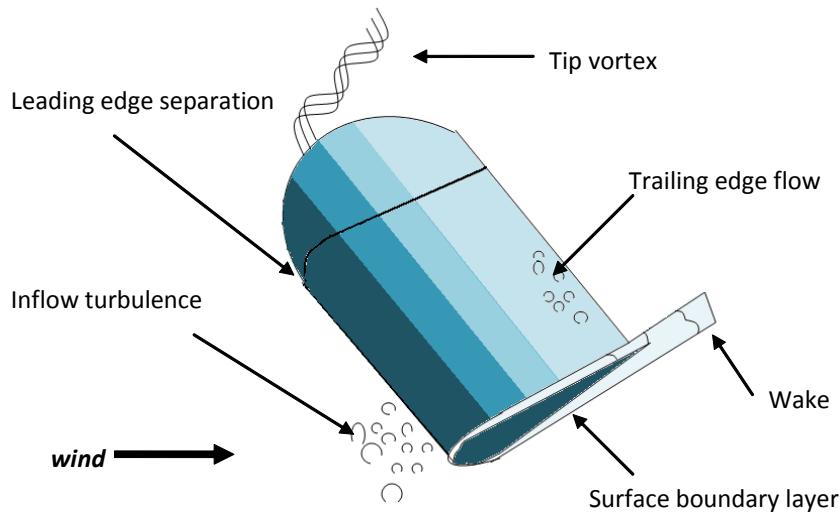

Figure 21: Airflow around a Rotor Blade

Mechanical noise from machinery inside the nacelle tends to be tonal in nature but can also have a broadband component. Potential sources of mechanical noise include the gearbox, generator, yaw drives, cooling fans, and auxiliary equipment. These components are housed within the nacelle, whose surfaces, if untreated, radiate the resulting noise. However modern wind turbines have nacelles that are designed to reduce internal noise, and rarely is the mechanical noise a significant portion of the total noise from a wind turbine.

7.2 Meteorology

Meteorological conditions can significantly affect sound propagation. The two most important conditions to consider are wind shear and temperature lapse. Wind shear is the difference in wind speeds by elevation and temperature lapse rate is the temperature gradient by elevation. In conditions with high wind shear (large wind speed gradient), sound levels upwind from the source tend to decrease and sound levels downwind tend to increase due to the refraction, or bending, of the sound (Figure 22).

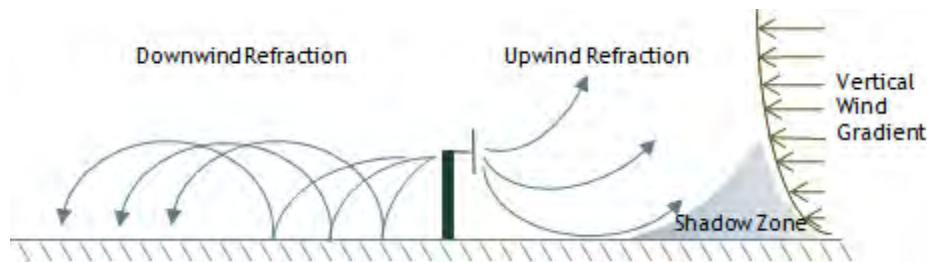

Figure 22: Schematic of the Refraction of Sound Due to Vertical Wind Gradient (Wind Shear)

With temperature lapse, when ground surface temperatures are higher than those aloft, sound will tend to refract upwards, leading to lower sound levels near the ground. The opposite is true when ground temperatures are lower than those aloft (an inversion condition).

The term “Stability Class” is used to describe how stable the atmosphere is. Unstable atmospheres can be caused by high winds and/or high solar radiation. This creates turbulence and tends to break up and dissipate sound energy. Highly stable atmospheres, which generally occur on clear nights with low ground-level wind speeds, tend to minimize atmospheric turbulence and are generally more favorable to down-wind propagation.

In general terms, sound propagates best under stable conditions with a strong temperature inversion. This occurs during the night and is characterized by low ground level winds.² Therefore, this is the default condition for modeling wind turbine sound.

7.3 Masking

As mentioned above, sound levels from wind turbines are a function of wind speed. Background sound is also a function of wind speed, i.e., the stronger the winds, the louder the resulting background sound. This effect is amplified in areas covered by trees and other vegetation. The sound from a wind turbine can often be masked by wind noise at downwind receivers because the frequency spectrum from wind is very similar to the frequency spectrum from a wind turbine. Figure 23 compares the sound spectrum measured during a 17 m/s wind event to a Gamesa wind turbine. As shown, the shapes of the spectra are very similar at the lower frequencies. At higher frequencies, the sounds from the masking wind noise are higher than the wind turbine. As a result, the masking of turbine noise is possible at higher wind speeds.

²The amount of propagation is highly dependent on surface conditions and the frequency of the sound. Under some circumstances highly stable conditions can show lower sound levels.

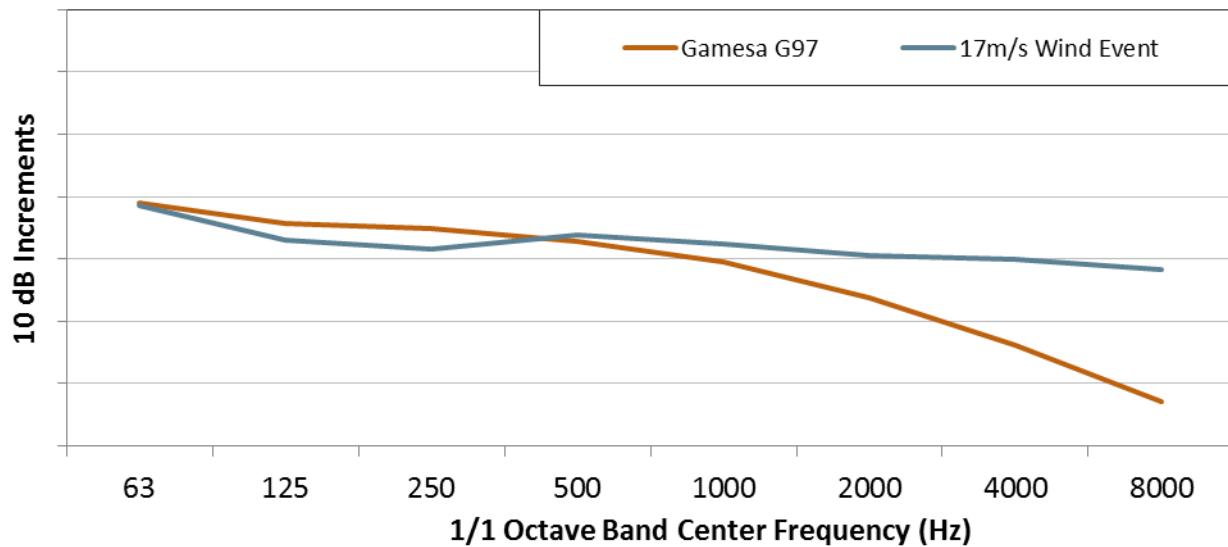

Figure 23: Comparison of Normalized Frequency Spectra from Wind and a Gamesa G97 Wind Turbine

It is important to note that while winds may be blowing at turbine height, there may be little to no wind at ground level. This is especially true during strong wind gradients (high wind shear), which mostly occur at night. This can also occur on the leeward side of ridges where the ridge blocks the wind.

7.4 Infrasound and Low Frequency Sound

Low frequency aerodynamic tonal noise is typically associated with downwind rotors on horizontal axis wind turbines. In this configuration, the rotor plane is behind the tower relative to the oncoming wind. As the turbine blades rotate, each blade crosses behind the tower's aerodynamic wake and experiences brief load fluctuations. This causes short, low-frequency pulses or thumping sounds called *blade impulsive noise*. Large modern wind turbines are “upwind”, where the rotor plane is upwind of the tower. As a result, this type of low frequency noise does not occur in all but the most swirling winds.

Infrasound is sound pressure fluctuations at frequencies below about 20 Hz. Sound below this frequency is generally not audible. Low frequency sound is in the audible range of human hearing, that is, above 20 Hz, but below 100 to 200 Hz depending on the definition.

A recent study comparing infrasound levels at rural homes near (approximately 1.5 km from) wind turbines, rural homes far from wind turbines, and urban homes, found that homes near wind turbines have infrasound levels similar to those located far (30 km) from wind turbines.

Infrasound levels at rural residences both near and far from wind turbines were not found to be higher than at urban residences and the study found fluctuations in infrasound to be primarily

caused by wind conditions.³ Another study compared infrasound levels near two wind farms with infrasound levels in the vicinity of a beach, a coastal cliff, a power station, and within the city of Adelaide, Australia. The study found infrasound levels approximately 200 meters from a wind turbine between 63 and 67 dBG. In comparison, infrasound levels were 75 dBG 25 meters from the high water line at a beach, 69 dBG 250 meters from a coastal cliff face, 57 dBG 8 km inland from the coast in a rural area, 74 dBG 350 meters from a gas powered substation, and 76 dBG 70 meters from the nearest road in downtown Adelaide. In short, infrasound levels were not abnormally high compared to everyday sound sources and even some natural sound sources.⁴

At very high sound levels (greater than 110 dB), infrasound can cause health effects such as decreased alertness and sleepiness.⁵ Infrasound can also rattle light-weight building partitions. However, modern wind turbines, with the hub upwind of the tower, do not create this level of infrasound. As a result, impact from infrasound is not expected.

Low frequency sound is a component of the sound generated by wind turbines. It is absorbed less by the atmosphere and ground than higher frequency sound. As with infrasound, high levels of low frequency sound can induce rattling in light-weight partitions in buildings. The American National Standards Institute standard, ANSI S12.2, "Criteria for Evaluating Room Noise", recommends that levels be kept below 65 dB at 16 Hz, 65 dB at 31.5 Hz, and 70 dB at 70 Hz inside the building to prevent moderately perceptible vibration and rattles.

Low frequency sound is primarily generated by the generator and mechanical components. Much of the mechanical noise has been reduced in modern wind turbines through improved sound insulation at the hub. Low frequency sound can also be generated by the blades at higher wind speeds when the inflow air is very turbulent. However, at these wind speeds, low frequency sound from the wind turbine blades is often masked by wind noise at the downwind receivers.

Finally, low frequency sound is absorbed less by the atmosphere and ground than higher frequency sound. Modeling took into account downward diffraction under a moderate nighttime temperature inversion and differing atmospheric absorption between low and high frequency sound.

8. SOUND PROPAGATION MODELING

8.1 Modeling Methodology

Modeling for the project was completed using the International Standards Organization ISO 9613-2 standard, "Acoustics – Attenuation of sound during propagation outdoors, Part 2: General Method of Calculation." The ISO standard states,

"This part of ISO 9613 specifies an engineering method for calculating the attenuation of sound during propagation outdoors in order to predict the levels of environmental noise at a distance from a variety of sources. The method predicts the equivalent continuous A-weighted sound pressure level ... under meteorological conditions favorable to propagation from sources of known sound emissions. These conditions are for downwind propagation ... or, equivalently, propagation under a well-developed moderate ground-based temperature inversion, such as commonly occurs at night."

The model takes into account source sound power levels, surface reflection and absorption, atmospheric absorption, geometric divergence, meteorological conditions, walls, barriers, berms, and terrain. Model input data is provided in Appendix A. The ISO standard was implemented in the Cadna A acoustical modeling software. Made by Datakustik GmbH, Cadna A is an internationally accepted acoustical model, used by many other noise control professionals in the United States and abroad.

Standard modeling methodology takes into account moderate nighttime inversions or moderate downwind conditions. For this study, we modeled the sound propagation in accordance with ISO 9613-2 with spectral ground attenuation and mixed ground ($G=0.5$).

A 25-meter by 25-meter grid of receivers was set up in the model covering 183 square miles around the project. In addition, over 800 discrete receivers were modeled at non-participating residences. A receiver is a point above the ground at which the computer model calculates a sound level. The coordinates for each receiver and all turbines are provided in Appendix B and Appendix C respectively.

As previously discussed, there are currently three turbine models under consideration, the Gamesa G114, the Vestas V110, and the GE 1.7-100. Modeling was conducted for each of these turbines using a 60 turbine layout, although the project will actually only construct the following number of turbines for each turbine model:

- Gamesa G114 – 50 turbines
- Vestas V110 – 56 turbines
- GE 1.7-100 – 59 turbines

By using the 60 turbine layout in the noise model, the results presented in this section are conservative and show that the project can meet the OPSB precedent noise standards using NROs

and curtailments as necessary. For non-participating residences, sound levels were mitigated to 48 dBA for daytime operations and 45 dBA for nighttime operations. In some cases, residences along Ohio 114 exceed these levels due to operations of the Blue Creek Wind Farm. When this was the case, sound levels from the proposed Northwest Ohio Wind Project were mitigated such that the increase in modeled sound levels at those residences would be less than 1 dB.

8.2 Gamesa G114 Model Results

Modeling results for the using the Gamesa G114 turbine are shown as sound contour maps in Figure 24 and Figure 25. Figure 24 provides the daytime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the daytime limit, and Figure 25 provides the nighttime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the project nighttime design goal. All residences shown are non-participating residences and the colored lines emanating from the wind turbines are color-coded isolines, where red represents 50 dBA, orange represents 45 dBA, yellow represents 40 dBA, light green represents 35 dBA, and dark green represents 30 dBA. Between the colored isolines are light gray isolines that represent 1 dB increments.

From OH 114 and northward, the highest daytime sound pressure level at a non-participating residence is 48 dBA, and the highest nighttime sound pressure level is 48, both due to the Blue Creek Wind Farm. With the NROs shown in Figure 24 and Figure 25, the sound levels from the Northwest Ohio Wind Project alone are less than 48 dBA during the day and less than 45 dBA at night at all non-participating residences.

The sound level in the 31.5 Hz and 63 Hz 1/1 octave band at the worst case receiver is 48 dB and 56 dB, respectively, which is below the levels specified in ANSI S12.2 that are necessary to cause moderately perceptible building vibrations.⁶

⁶ ANSI S12.2 also has standards for perceptible building vibration at 16 Hz and 31.5 Hz, but no information is available from Gamesa on sound power at these frequencies. Assuming an increase of 3 dB per octave band, however, the ANSI S12.2 standard would be met at these lower octave bands as well.

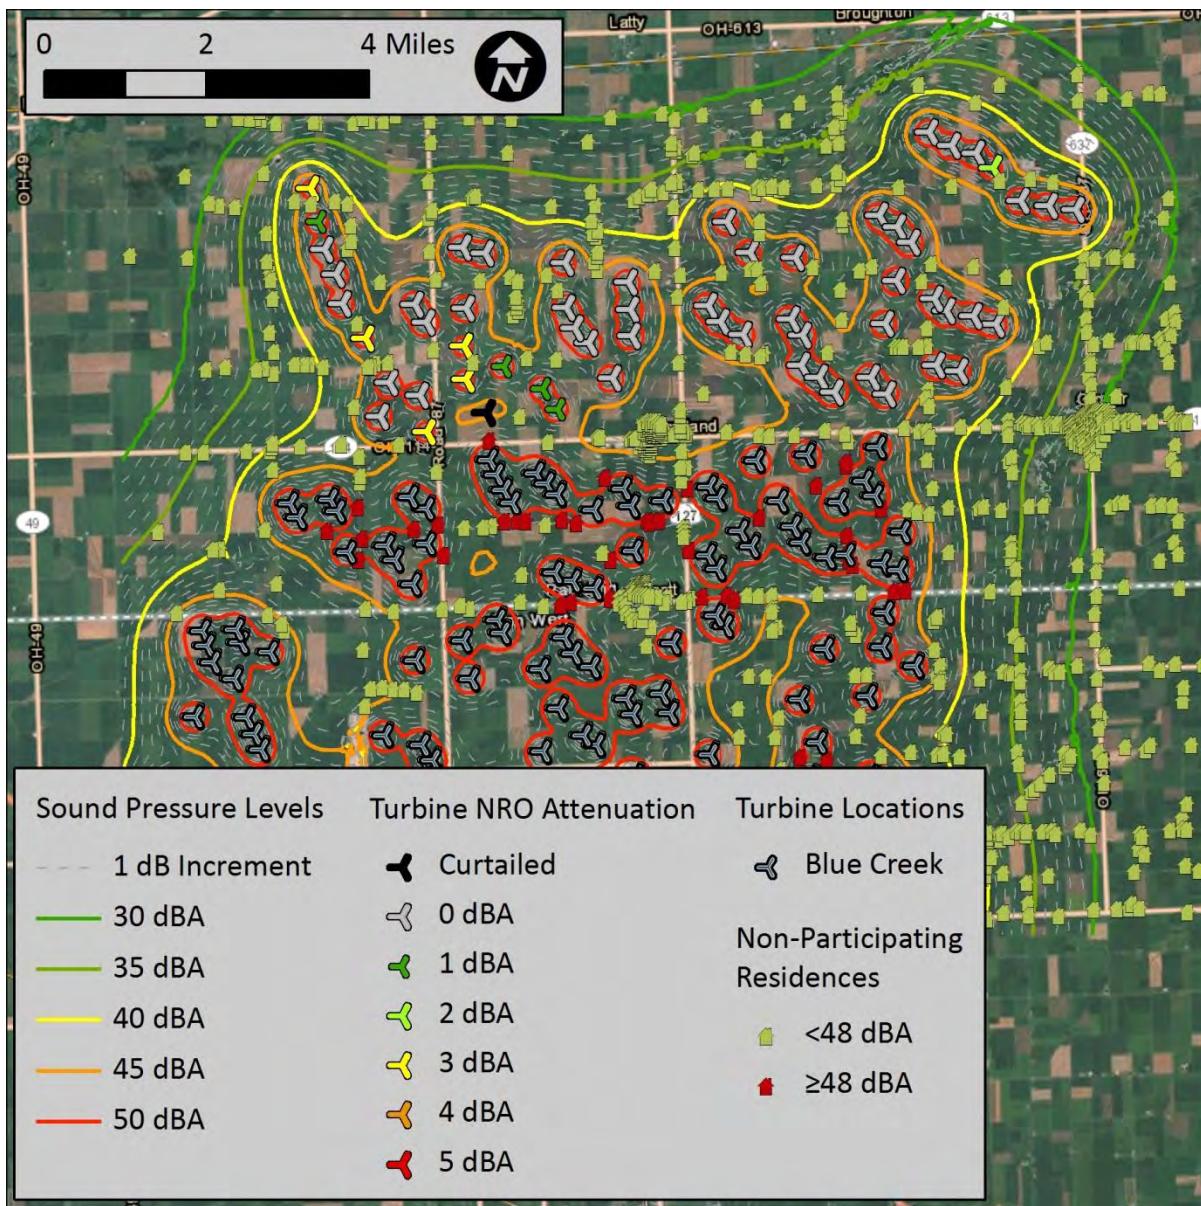

Figure 24: Mitigated Sound Propagation Modeling Results, Daytime, G114

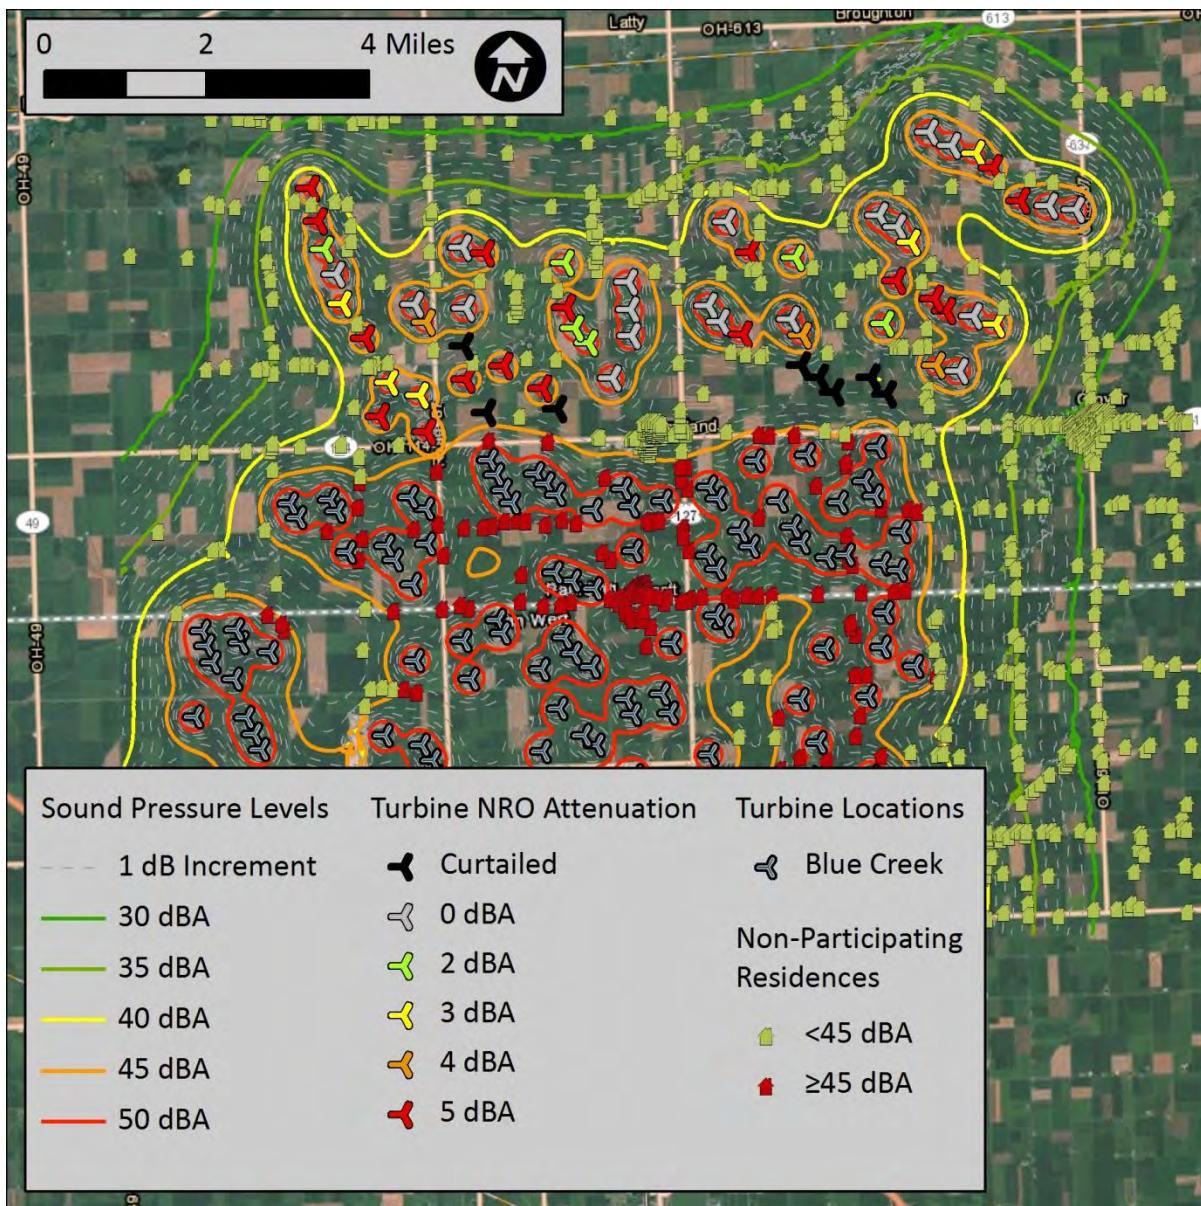

Figure 25: Mitigated Sound Propagation Modeling Results, Nighttime, G114

8.3 Vestas V110 Model Results

Modeling results for the using the Vestas V110 turbine are shown as sound contour maps in Figure 26 and Figure 27. Figure 26 provides the daytime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the daytime limit, and Figure 27 provides the nighttime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the project nighttime design goal. All residences shown are non-participating residences and the colored lines emanating from the wind turbines are color-coded isolines, where red represents 50 dBA, orange represents 45 dBA, yellow represents 40 dBA, light green represents

35 dBA, and dark green represents 30 dBA. Between the colored isolines are light gray isolines that represent 1 dB increments.

From OH 114 and northward, the highest daytime sound pressure level at a non-participating residence is 48 dBA, and the highest nighttime sound pressure level is 48, both due to the Blue Creek Wind Farm. With the NROs shown in Figure 26 and Figure 27, the sound levels from the Northwest Ohio Wind Project alone are less than 48 dBA during the day and less than 45 dBA at night at all non-participating residences.

The sound level in the 31.5 Hz and 63 Hz 1/1 octave band at the worst case receiver is 59 dB and 57 dB, respectively, which is below the levels specified in ANSI S12.2 that are necessary to cause moderately perceptible building vibrations.

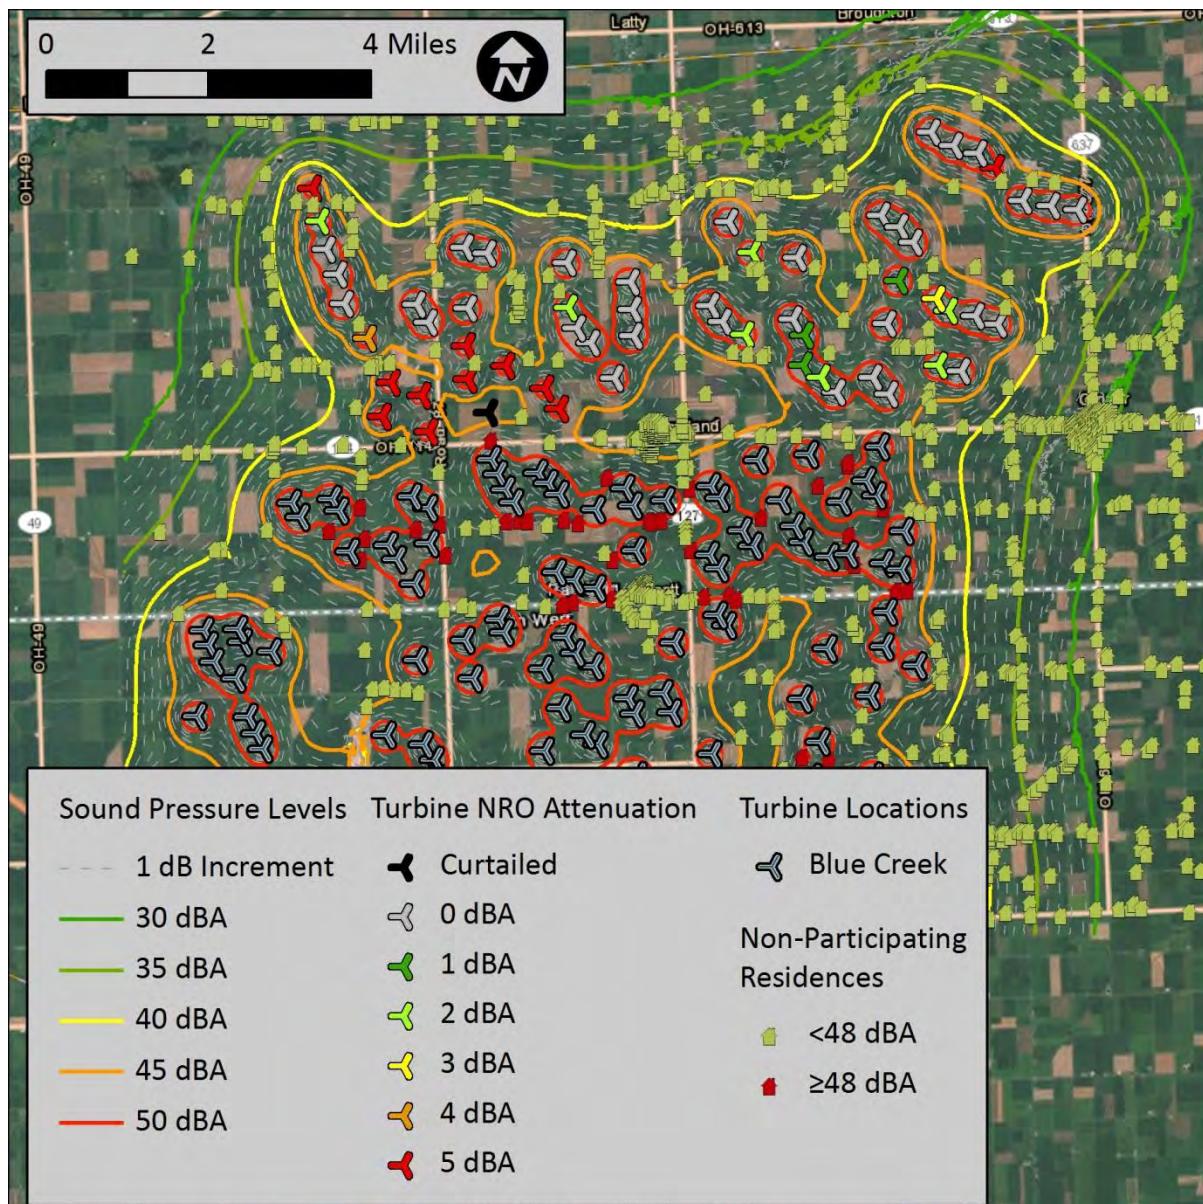

Figure 26: Mitigated Sound Propagation Modeling Results, Daytime, V110

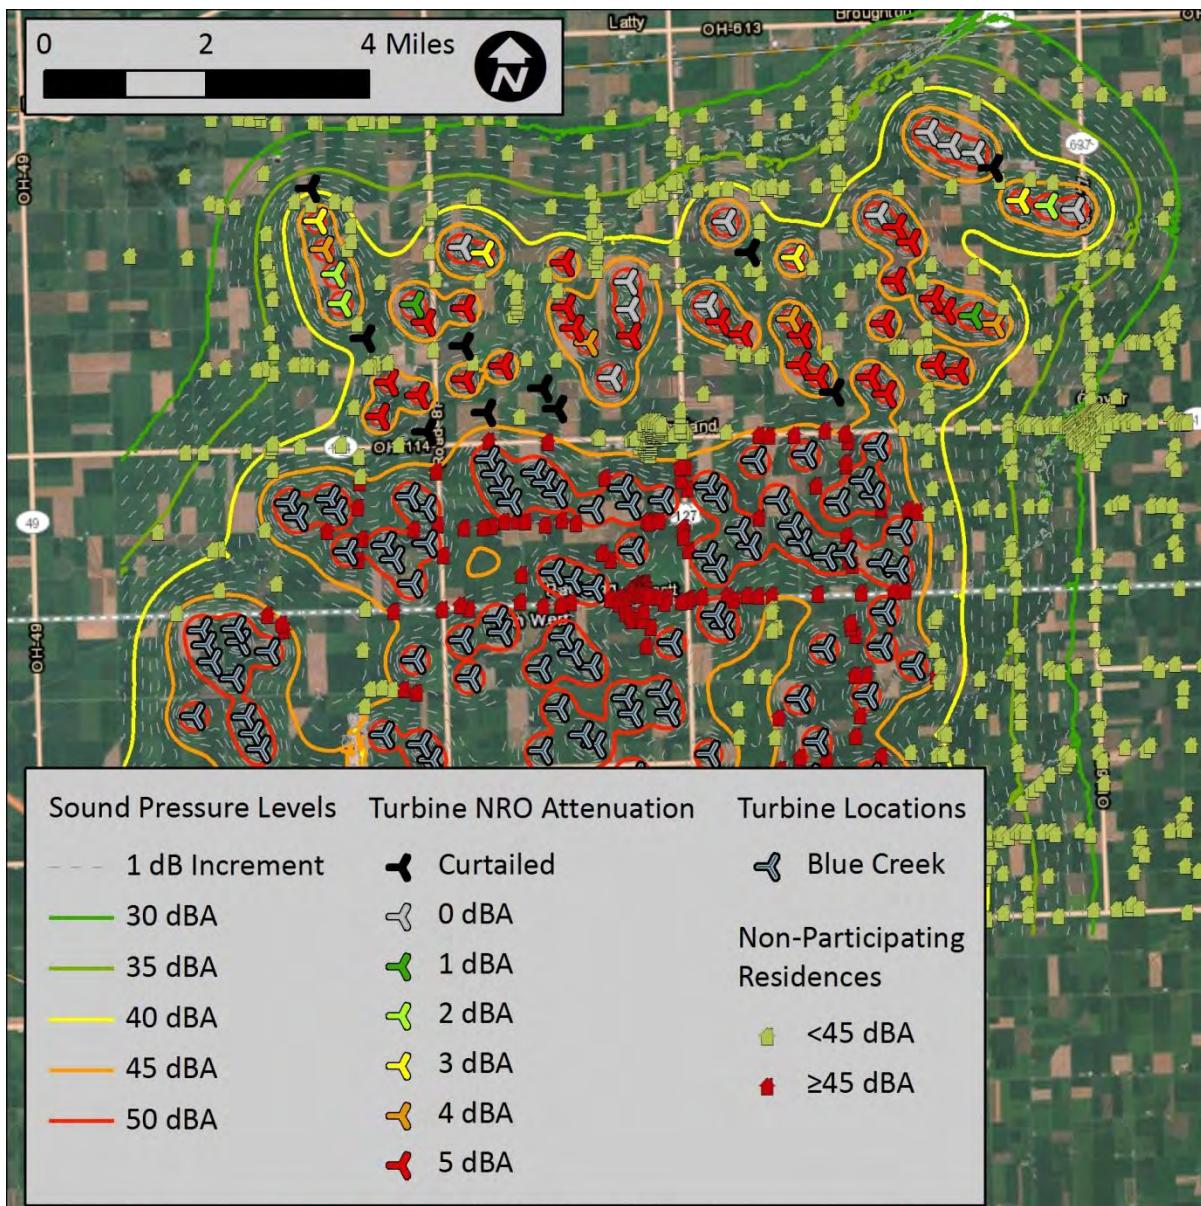

Figure 27: Mitigated Sound Propagation Modeling Results, Nighttime, V110

8.4 GE 1.7-100 Model Results

Modeling results for the using the GE 1.7-100 turbine are shown as sound contour maps in Figure 28 and Figure 29. Figure 28 provides the daytime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the daytime limit, and Figure 29 provides the nighttime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the project nighttime design goal. All residences shown are non-participating residences and the colored lines emanating from the wind turbines are color-coded isolines, where red represents 50 dBA, orange represents 45 dBA, yellow represents 40 dBA, light green represents

35 dBA, and dark green represents 30 dBA. Between the colored isolines are light gray isolines that represent 1 dB increments.

From OH 114 and northward, the highest daytime sound pressure level at a non-participating residence is 48 dBA, and the highest nighttime sound pressure level is 48 dBA, both due to the Blue Creek Wind Farm. With the NROs shown in Figure 28 and Figure 29, the sound levels from the Northwest Ohio Wind Project alone are less than 48 dBA during the day and less than 45 dBA at night at all non-participating residences.

The sound level in the 31.5 Hz and 63 Hz 1/1 octave band at the worst case receiver is 59 dB and 59 dB, respectively, which is below the levels specified in ANSI S12.2 that are necessary to cause moderately perceptible building vibrations.

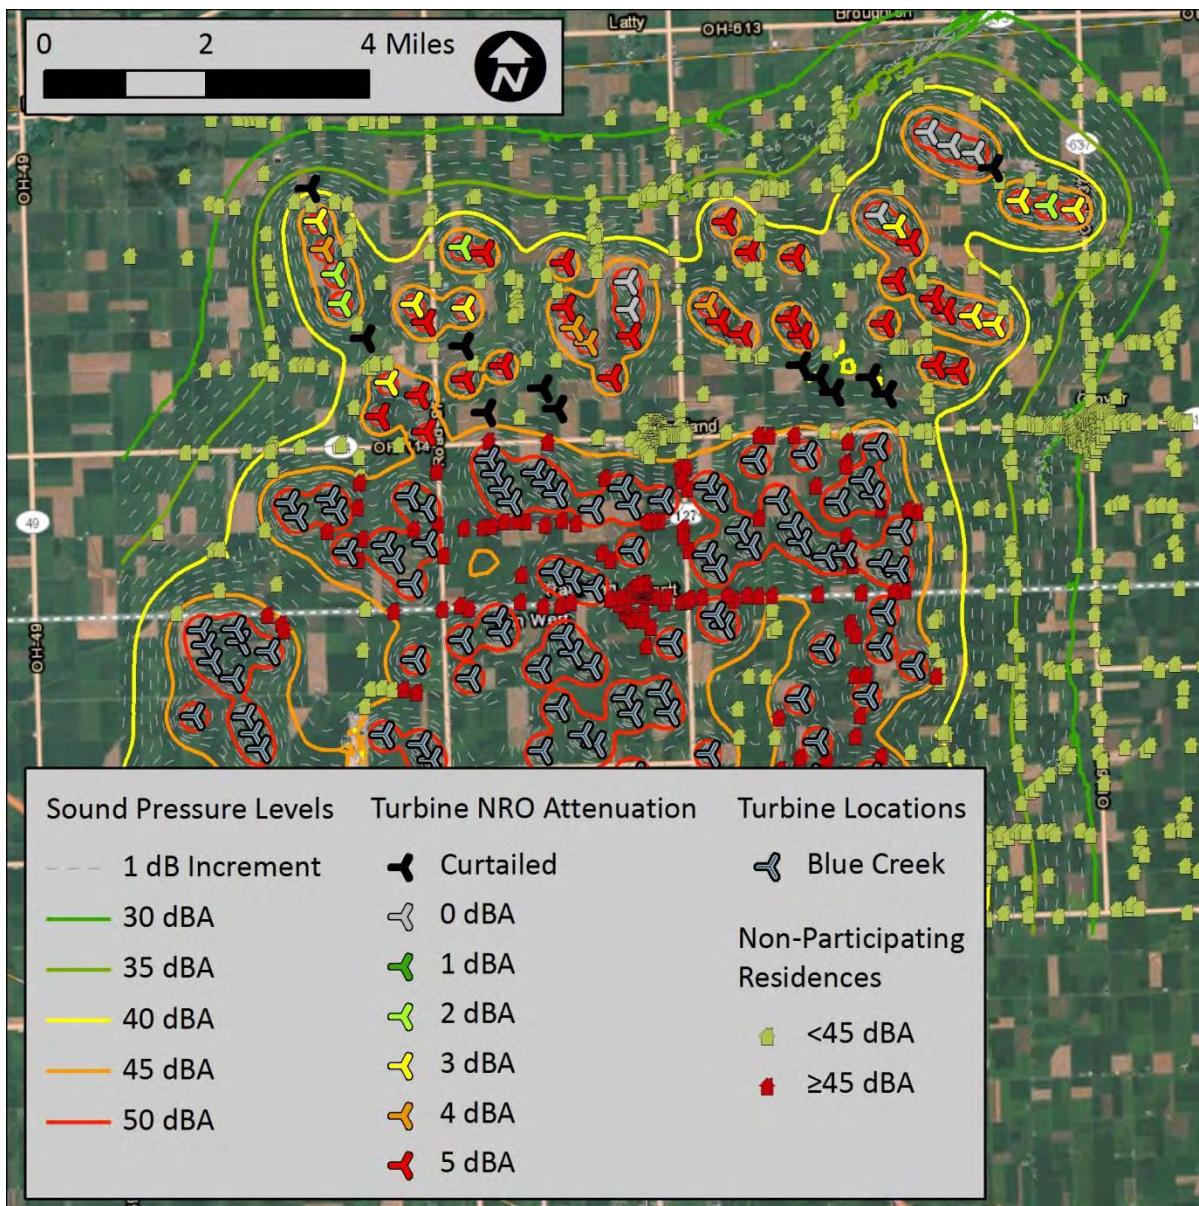

Figure 29: Mitigated Sound Propagation Modeling Results, Nighttime, GE 1.7-100

9. CONSTRUCTION IMPACTS

The construction of the turbines will take place primarily at the turbine sites. While there may be activity closer to residences for road construction and utility work, such work will be of a relatively short duration.

The equipment used for the construction will be varied. Some of the louder pieces of equipment are shown in Table 4 along with the approximate maximum sound pressure levels at 50 feet (15.2 m)

and 985 feet (300 m). 985 feet is the approximate distance of the closest non-participating residence from a turbine site.

Blasting is not anticipated to be needed. Should blasting be required, it will occur intermittently and only for limited periods of time.

Major construction work, such as clearing for the access roads, will occur primarily during the day; however, minor construction work may extend earlier or later.

Due to the setbacks involved and the limited duration of the activities, construction noise should not pose undue quality of life concerns.

Table 4: Maximum Sound Levels from Various Construction Equipment

Equipment	Sound Pressure Level at 50 feet (dBA)	Sound Pressure Level at 985 feet (dBA)*
M-250 Liftcrane	83	51
2250 S3 Liftcrane	78	47
Excavator	83	54
Dumptruck being loaded	86	58
Dumptruck at 25 mph accelerating	76	49
Tractor Trailer at 25 mph accelerating	80	54
Concrete Truck	81	50
Bulldozer	85	54
Rock drill	100	67
Loader	80	46
Backhoe	80	49
Chipper	96	68

*Shortest distance from any one wind turbine to any one non-participating residence.

10. CONCLUSIONS

Northwest Ohio Wind Project, a proposed National Wind development, is a 60-turbine wind power project to be located in Paulding County, Ohio. In preparation for Ohio Power Siting Board (OPSB) filing, RSG was hired to perform a noise impact assessment consistent with OPSB precedents set for similar projects. Conclusions are as follows:

- 1) There are no quantitative noise standards that apply to this project. The precedent from Buckeye II and other wind projects has set the applicable noise limit modeled at a home to 5 dBA above the facility area nighttime ambient noise levels (Leq). A nighttime design goal for this project has also been set at 45 dBA.

- 2) The average nighttime background sound level, measured from 5 sites around the project was 43 dBA, setting the sound level limit to 48 dBA for the project.
- 3) Sound propagation modeling was performed in accordance with ISO 9613-2 at over 800 discrete receivers that surround the project, with spectral ground attenuation and a ground factor of $G = 0.5$ (mixed ground).
- 4) A turbine model has not been chose for this project. The Gamesa G114, Vestas V110, and the GE 1.7-100 were all modeled with sound power levels of 106 ± 2 dBA, 107.5 ± 2 dBA, and 107 ± 2 dBA. While only 50 turbines would be constructed if the G114 is used, 56 turbines if the V110 is used, and 59 turbines if the GE 1.7-100 is used, 60 turbines were conservatively modeled in this study for each turbine model.
- 5) With NROs (Noise Reduced Operations) applied to the turbines, the highest modeled daytime sound level at a non-participating receiver was 48, which was due to sound emissions from the adjacent Blue Creek Wind Farm. The highest modeled daytime sound level at a non-participating receiver attributable to the Northwest Ohio Wind Project is 48 dBA.
- 6) With NROs applied to the turbines, the highest modeled nighttime sound level at a non-participating receiver was 48, which was due to sound emissions from the adjacent Blue Creek Wind Farm. The highest modeled daytime sound level at a non-participating receiver attributable to the Northwest Ohio Wind Project is 45 dBA.
- 7) Once the final turbine model and layout is determined, final sound modeling can be conducted to determine the final NRO/curtailment schedule that is necessary to meet the noise limits.
- 8) The modeled levels of low frequency sound will be below recognized standards for low frequency sound intended to protect against perceptible building vibration.
- 9) Other than extended concrete pours and similar events, major construction will take place during normal business hours. Aside from road construction, these activities will take place at approximately 1,000 feet or more from non-participating residences.

Section 4906-17-08 Social and Ecological Data, (A) Health and Safety (2) noise is supplemented with the following submittal to accommodate acoustic sound studies completed for the site.

(2) Noise

Noise is commonly used to describe unwanted sound. Sound is an audible variation of air pressure, and can vary in both intensity and frequency. The intensity of a sound wave is measured on a logarithmic scale in units called decibels [dB]. Each 10 dB increase is a doubling of the intensity. Because people are more sensitive to sounds of certain frequencies, the A-weighted [dB(A)] scale is used to discuss sound impacts on humans. The dB(A) scale gives more weight to sounds within the normal human hearing range and less weight to sounds that are at the upper and lower range of audible frequency. Table 8-3 shows sound levels associated with some common sources and/or locations:

Table 8-3: Common Sound Sources and Sound Levels	
Sound in dB(A)	Source
140	Jet Engine (at 80 feet)
130	Jet Aircraft (at 330 feet)
120	Rock and Roll Concert
110	Pneumatic Chipper
100	Jointer/Planer
90	Chainsaw
80	Heavy Truck Traffic
70	Business Office
60	Conversational Speech
50	Library
40	Bedroom
30	Secluded Woods
20	Whisper

Typical ambient night time sound levels for windy rural areas are in the low-to-mid 30 dB(A) range. Ambient levels up to 60 dB(A) may exist near roads, farmsteads and other areas of human activity during normal daytime work hours (USEPAEPA 1974). The windy conditions in the Project area will tend to increase the natural ambient sound levels and mask other sound sources.

Paulding County is a rural agricultural area. Although sound levels may be sporadically elevated in localized areas due to roadway noise, periods of human activity, or farming operations, overall existing ambient sound levels are expected to be relatively low. Background sound levels vary both spatially and temporally, depending on proximity to area sound sources, roadways, and natural sounds. Principal contributors to the existing acoustic environment likely include motor vehicle traffic, mobile farming equipment, farming activities such as plowing and irrigation, all-terrain vehicles, local roadways, periodic aircraft fly-overs and rail movements, and natural sounds such as birds, insects, and leaf or vegetation rustle during elevated wind conditions in areas with established trees or established crops. Diurnal effects result in sound levels that are typically quieter during the night than during the daytime, except during periods when evening and nighttime insect noise dominates in warmer seasons.

In areas with elevated background sound levels, sound may be obscured through a mechanism referred to as acoustic masking. For example, crickets chirping, farming activities, and wind-generated ambient noise as airflow interacts with foliage can contribute to this masking effect. The variation of background noise with wind speed is dependent on several site-specific factors including topographic shielding, and locations of established woodlots and open areas. There are also seasonal differences in background sound levels. The loss of leaf cover during fall decreases background sound masking effects. Also, during wintertime windows are typically closed de-creasing the transmission of sound.

Westwood reviewed regulations at the federal, state, and county level. There are no regulations with numerically defined decibel limits directly applicable to the Facility. There are, however, precedents set by the Ohio Power Siting Board (OPSB) for other

wind power projects within the state. Recently, in the Buckeye II Wind Farm project, the OPSB placed the following condition:

“The facility shall be operated so that the facility noise contribution does not result in noise levels at the exterior of any currently existing nonparticipating sensitive receptor that exceed the project area ambient nighttime Leq of 39 dBA, plus five dBA. During daytime operations only, 7:00 a.m. to 10:00 p.m., the facility may operate at the greater of: (a) the project area ambient nighttime Leq, 39 dBA, plus five dBA; or (b) the validly measured ambient (Leq), plus five dBA, at the location of the sensitive receptor.”

This condition for the Buckeye II Wind Farm set the applicable nighttime noise limit for the development to 5 dBA above the facility area nighttime ambient noise levels (Leq) and the same limit is used for daytime operations unless a greater ambient noise levels (Leq) at the location of the sensitive receptor is known, in which case the daytime limit would be the greater ambient noise level (Leq) at the sensitive receptor location, plus 5 dBA.

Based on ambient sound monitoring at five locations around the project area (Section 5), the average nighttime (Leqnights) is 43 dBA. The nighttime limit for this project would be 48 dBA under the Buckeye II project precedent. This limit also applies to the daytime except in instances where the daytime ambient noise level (Leq) is higher than 43 dBA at a sensitive receptor. Based on ambient sound monitoring at the five locations around the project area (Section 5), the daytime ambient level ranged from 39 to 59 across the five monitoring locations. The daytime limit for the project would be between 48 dBA (the nighttime limit) and 64 dBA (highest daytime ambient plus 5 dBA) depending on the sensitive receptor.

Although prior board precedent would allow a project limit of 48 dBA, the project will use as a design goal of 45 dBA for nighttime operations. This is based on World Health Organization (WHO) guidelines. In their “Guidelines for Community Noise” (1999), the WHO reviewed the most current research on the health impacts of noise to develop guideline sound levels for communities. To quote the foreword of the report, “The scope of WHO’s effort to derive guidelines for community noise is to consolidate actual

scientific knowledge on the health impacts of community noise and to provide guidance to environmental health authorities and professionals trying to protect people from the harmful effect of noise in non-industrial environments.” The WHO concluded that the sound level averaged over the eight nighttime hours should not exceed 45 dBA, (also indicated as 45 dBA Leq(8)), to protect against health impacts, specifically sleep disturbance, due to noise.

Construction Noise Levels

Noise from construction activities will likely cause a temporary impact to some of the homes in proximity to the Project area. These construction sounds can vary significantly depending on the age and condition of equipment and the particular stage of construction and equipment necessary to that particular stage. The expected noise levels at the nearest property boundary will be variable and are expected to be within the ranges found in Table 8-4.

(i) Dynamiting activities

Applicant will not use blasting during Facility construction.

(ii) Operation of earthmoving equipment

Site clearing: This first phase typically includes establishing temporary site offices, storage areas, and construction staging areas as well as the installation of erosion and sedimentation control measures.

Excavation: This phase typically includes the construction and preparation of access roads, laydown yards, and excavation for turbine foundations.

Foundation work: This phase consists of the construction of the concrete turbine foundations and the network of collection lines.

(iii)Driving of piles

Applicant will not use driving of piles during Facility construction.

(iv) Erection of structures

Turbine installation: The final phase includes the delivery and erection of the turbines. The primary equipment utilized during this phase includes flat-bed semis transporting the materials to the turbine site via access roads and the track-mounted erection crane.

(v) Truck traffic

Over-the-road transport trucks will deliver the majority of equipment and components to the site. The majority of such materials will be delivered directly to the turbine site for off-loading and installation. Some materials will be delivered to the lay-down yard for staging until required for a particular state of construction.

(vi) Equipment installation

The typical pieces of equipment used during construction and their average near (50 feet) noise levels are summarized in Table 8-4.

Table 8-4. Noise Emission Levels Typical of Construction Equipment

Equipment	Estimated Sound Level at 50 feet (dBA)	Estimated Sound Level at 2000 feet (dBA)
Backhoe	80	48
Grader	85	53
Crane	85	53
Loader	85	53
Roller	75	50
Bulldozer	85	51-56
Truck	88	52
Compressor	80	48
Concrete Pump	77	45

Operational Noise Levels

Applicant performed Long term sound level monitoring at five locations in the project area from May 24, 2013 until May 31, 2013. Temperatures during the

monitoring period ranged 41° to 86° F, and average one-minute wind speeds (5 foot height) ranged from 0 to 21 mph with gusts as high as 26 mph. Most of the periods of higher winds occurred on May 28, 29, and 30. There were some light rainy periods on May 27 (6:30 a.m. to 10:00 a.m. & 1 p.m. to 6 p.m.) and May 28 (4:30 a.m. to 6:30 a.m.).

Sound level data was collected using either ANSI/IEC Type 2 Rion NL-22 sound level meters or ANSI/IEC Type 1 Cesva SC310 sound level meters. The Rions were set to log 1 second equivalent A-weighted sound levels every one-second and the Cesvas were set to log 1/3 octave band sound levels every one-second. The Rions were set to record audio clips of sound events that exceeded 55 dBA and the Cesvas were connected to Roland R-05 or R-09 HR sound recorders. The microphones were mounted on a 1.5 meter (5 foot) tall wooden stakes and covered with a 7 inch ACO-Pacific weather resistant windscreens.

Data was summarized into 10-minute periods. All periods that contained precipitation and sustained wind speeds above 11 mph were eliminated during post-processing. The modeled maximum L50 sound level at 1,000 feet for a single turbine using the above assumptions is shown in Table 8-5:

Table 8-5: Modeled Maximum Sound Levels: Turbine Sound [dB(A)]		
Turbine Model	dB(A) daytime	dB(A) nightime
GE 1.7-100 1.MW turbine	48	45
Gamesa G114-2.0MW turbine	48	45
Vestas V100-1.8MW turbine	48	45

Cumulative sound impact analysis results showing the highest modeled sound power level at any home in the Project area for the turbine layout are in Table 8-6:

**Table 8-6: Cumulative Modeled Maximum Sound Levels:
Turbine Sound [dB(A)]**

Turbine Model	dB(A)
GE 1.7-100 1.MW turbine	48
Gamesa G114-2.0MW turbine	48
Vestas V100-1.8MW turbine	48

Modeling results for all three turbines are shown as sound contour maps in Appendix I. Separate figures for each turbine provide the daytime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the daytime limit, and the nighttime results with the required NRO modes or curtailments indicated for each proposed turbine to meet the project nighttime design goal. All residences shown are non-participating residences and the colored lines emanating from the wind turbines are color-coded isolines, where yellow represents 50 dBA, light green represents 45 dBA, and dark green represents 40 dBA. Between the colored isolines are light gray isolines that represent 1 dB increments.

From OH 114 and northward, the highest daytime sound pressure level at a non-participating residence is 48 dBA, and the highest nighttime sound pressure level is 48, both due to the Blue Creek Wind Farm. With the NROs shown in Appendix I, the sound levels from the Northwest Ohio Wind Project alone are less than 48 dBA during the day and less than 45 dBA at night at all non-participating residences.

The sound level in the 31.5 Hz and 63 Hz 1/1 octave band at the worst case receiver is 59 dB and 59 dB, respectively, which is below the levels specified in ANSI S12.2 that are necessary to cause moderately perceptible building vibrations.

During operation of the Facility, the primary source of sound from the step-up facility will be the transformer, which can emit a low frequency humming sound. An Option Agreement for purchase of up to 25 acres for the step-up facility has

been executed between Applicant and the parcel landowner. The final location of the step-up facility within that parcel has not been finalized and is contingent upon further civil design work, collector line routing, and coordination with the transmission owner in locating the interconnection facilities.

The nearest occupied home to locations being considered for the step-up facility within the parcel is located more than 500 feet away and sound associated with normal operation of the step-up facility is not expected to be audible at this farmstead/home.

(b) Location of Noise Sensitive Areas

The predicted sound contour plots in Appendix I depict residential structures within one mile of the Facility. There are no libraries, hospitals, nursing homes or assisted living and health care facilities within one mile of the turbines. However, there are XX churches located within one mile of the Facility: Edgerton Wesleyan Church (Woodburn), Jehovah's Witnesses Kingdom (Antwerp), and St. James Lutheran Church (Payne). The Wayne Trace high school is located within the project footprint as shown on Figure 3-1. Places of worship are shown on Figure 8-1.

(c) Mitigation of Noise Emissions

Over the last decade, the wind industry has invested heavily in reducing turbine noise through improvements in turbine technology, engineering, and insulation. According to a 2006 report prepared by the Renewable Energy Research Laboratory, sound levels emitted by turbines have decreased as technology has advanced. Improvements in blade airfoil efficiency have resulted in more wind energy being converted into rotational energy, and less into acoustic energy. Vibration dampening and improved mechanical design have also significantly reduced noise from mechanical sources. Furthermore, aerodynamic sound generation is very sensitive to speed at the blade tips. Modern variable speed turbines, like those proposed for the Facility, rotate at slower speeds in low winds,

increasing in higher winds. This results in quieter operation in low winds when compared to older, constant speed turbines (Rogers et al., 2006). These findings are consistent with a recent Department of Energy Report (2008), which concluded, "advances in engineering and insulation ensure that modern turbines are relatively quiet; concerns about sound are primarily associated with older technology, such as the turbines of the 1980s, which were considerably louder."

Although residential sound impacts are anticipated to be minor, additional mitigation measures will include the following:

- The turbines will operate under NROs or full curtailment to meet the noise requirements imposed by the OPSB. The current modeling assumes that all 60 locations will be operational as the most conservative assumption. Final selection of a turbine and the corresponding locations will result in total project noise lower than the current analysis based on eliminating up to 10 locations. Following final turbine selection modifications to turbine layout will be adopted to attenuate sound levels.
- General construction activities will be typically limited to the hours of 7:00 a.m. to 7:00 p.m., or until dusk when sunset occurs after 7:00 p.m. Construction activities that do not involve noise increases above ambient levels at sensitive receptors may be performed outside of daylight hours when necessary. Applicant will notify property owners or affected tenants within the meaning of OAC Section 4906-5-08(C)(3), of upcoming construction activities including potential for nighttime construction activities.
- Notifying landowners of certain construction sound impacts in advance, e.g., if blasting becomes necessary..

In addition, if adverse sound impacts are identified during turbine operations that exceed the acoustic guidelines, a reasonable complaint resolution procedure will be implemented to ensure any complaints regarding construction or operational

sound are adequately investigated and resolved. Facility staff will formally document all noise complaints, which will then be investigated by on-site Facility staff. This will involve a review of equipment performance to determine if sound levels fall outside normal tolerances; any faulty equipment identified will be repaired.
