## **APPENDIX D**

### **General Earthwork Recommendations**

## **APPENDIX D** **GENERAL EARTHWORK RECOMMENDATIONS**

Earthwork is most efficiently accomplished using large, heavy-duty equipment, unimpeded by obstacles. Consequently, it is preferable to complete as much of this work as is possible prior to initiating other phases of construction, such as footing excavation and installation of underground utilities. The following are general recommendations concerning earthwork construction and may not be applicable to site-specific conditions. Furthermore, the contractor is responsible in selecting and implementing the most appropriate construction techniques (e.g., construction means, methods, sequences or procedures, or for safety precautions or programs) for each site-specific condition(s).

### **1. Stripping, clearing and grubbing**

In areas where fill is to be placed to support structures, drive and parking areas, the following is proposed:

Strip and remove all sod, topsoil, and organic contaminated soils.

Remove all trees and shrubs, designated to be cleared, inclusive of grubbing roots of larger trees.

Remove all trash, debris, rubble, existing random fill, soil softened by standing water, and any other soft soil as determined necessary by the geotechnical engineer. The fill placement should begin on firm, relatively unyielding foundation material.

The fill foundation should be stripped and cleared beyond the limits of the structure by a distance equal to not less than the thickness of the fill below the structure foundation plus 10 feet. For drives and parking areas, the fill foundation should be stripped and cleared for a distance of at least 5 feet beyond the limits of the pavement.

### **2. Fill Material – Composition**

Material satisfactory for use as fill includes clayey silt and silty (lean) clay soils or sand and gravel, free of topsoil, organic or other decomposable matter, rocks having a major dimension greater than 6 inches, or frozen soil.

Soils having a maximum dry density of less than 90 pounds per cubic foot as determined by the moisture-density relationship are not considered suitable for use as fill.

Soils described as SILT (USCS ML, MH or ODOT A-4B) are considered questionably suitable for use as fill material because the stability of these materials is very sensitive to increases in moisture. These soils should not be placed within three feet of the top of the subgrade.

### **3. Fill Material – Moisture**

Predominately fine grained fill materials (lean clayey soils) are recommended to contain moisture contents within 3 percent (above or below) the optimum moisture as determined by the moisture-density relationship (ASTM International D698), or less if found to be needed to obtain stability below the compaction equipment. This provides the best assurance of establishing not only adequate density for ultimate support of construction but also provides stability of the compacted soil under the dynamic loading induced by the heavyweight construction equipment during placement.

Sand and gravel fill material is not as sensitive to moisture content with regards to stability. Therefore, we recommend no specified limitation, as long as specified density and stability can be established.

#### **4. Moisture Adjustment**

If the moisture content of the material from the fill source or native subgrade is not appropriate to establish density, moisture adjustment of the material will be required.

If the moisture content of the fill being placed or the native subgrade is too high, appropriate adjustment entails spreading and exposing to the sun and wind for drying and using equipment such as a disc and/or a grader. This may not be feasible during wet seasonal conditions. Wet soils will pump and may cause excessive rutting under heavy equipment traffic. Therefore, improvements to the subgrade may be achieved by undercutting and replacing with suitable fill (possibly in combination with a non-woven geotextile or biaxial geogrid) or stabilization with lime or cement. The most appropriate subgrade improvement technique should be determined at the time of construction.

If the moisture content of the fill is too low, a water truck with a sprinkler bar may be required. After sprinkling, the soil should be thoroughly mixed with a disc and/or a grader.

#### **5. Equipment**

Equipment to compact the fill should be heavy duty with a steel drum roller having a minimum effective unit weight of 10 tons. For example:

Fine-grained materials (clayey silts and lean clays) may be efficiently compacted using a sheepsfoot roller comparable to a Caterpillar 815 self-propelled roller.

Coarse-grained materials (sand and gravel) having little or no silt and clay sizes may be efficiently compacted using a heavy, self-propelled, vibratory smooth wheel roller.

Coarse-grained materials having about 10% or more silt and clay sizes may be efficiently compacted using a sheepsfoot roller comparable to a Caterpillar 815 self-propelled sheepsfoot roller.

#### **6. Lift Thickness**

Fill should be placed in horizontal layers, 8-inch loose thickness, compacted uniformly to approximately 6-inch thickness.

If equipment is used which is lighter weight than recommended above, lift thickness should be appropriately thinner.

#### **7. Fill Density**

In areas to support access roads and within the pad, the fill and backfill should be compacted to the density requirements as recommended in the main body of the report

#### **8. Season of Earthwork**

Weather conditions are very important to efficiency in working soils. Generally, earthwork is accomplished most efficiently between May and November. Cold periods may hamper moisture adjustment. If the temperature is below 32 degrees Fahrenheit ( $^{\circ}$ F) for prolonged periods, frozen

material on the fill surface must be removed before subsequent lifts may be placed. Also, densification of fill is more difficult when air temperatures are below freezing. Granular material, such as bank run sand and gravel is somewhat less sensitive to weather conditions but is not immune from difficulties that may be presented by precipitation and low temperatures.

#### **9. Trench Backfill**

Trench backfill should be controlled compacted fill, placed in accordance with recommendations presented above and as engineered for thermal properties in collection systems

It is recommended that suitable granular material be used to backfill trenches that traverse beneath buildings, drives, or parking areas.

#### **10. Proof Rolling**

Upon completion of stripping, clearing, and grubbing; the areas planned to support pavement or building floor slab shall be proof rolled in accordance with ODOT Item 204 to identify any soft, weak, loose, or excessively wet subgrade conditions. At a minimum, the proof rolling should be completed with a minimum 20-ton loaded tandem axle dump truck. The vehicle should pass in each of two perpendicular directions covering the proposed work area. Any observed unsuitable materials should be undercut and replaced with suitable fill as directed by the geotechnical engineer.

#### **11. General**

All fill should be placed and compacted under continuous observation and testing by a soils technician under the general guidance of the geotechnical engineer.

## **APPENDIX E**

### **Generalized Geotechnical Exploration Work Plan**

## APPENDIX E

### GENERALIZED GEOTECHNICAL EXPLORATION WORK PLAN

A geotechnical engineer shall prepare a proposal for a geotechnical site exploration in general accordance with the suggested scope of work provided below. The geotechnical engineer shall be qualified in geotechnical investigations. The geotechnical exploration program suggested below (e.g., boring frequency, location and depth) should be adjusted by the geotechnical engineer based on their experience and to allow for specific geological, topographic, and drainage conditions of the site.

#### **PROJECT DESCRIPTION**

A geotechnical exploration will be performed at the proposed Project Boundary in Seneca and Sandusky Counties, Ohio. The project involves planned construction of wind turbine generators at various locations (Sites) for the Republic Wind Farm Project. Upon completion of the geotechnical exploration suitable foundation systems will be reviewed that will work with the Site conditions as determined by the geotechnical exploration and design preferences provided by the Client. The foundation types that will be considered include spread footings, ring foundation, P&H foundations, and pile supported foundations.

The purpose of the geotechnical exploration is to obtain geologic information and to determine relevant engineering properties of the Site soils. A review of generalized geologic references, including ODNR Well Logs and ODNR Groundwater Resource Maps, suggest the Project Boundary is underlain by lacustrine and ground moraine deposits with dolomite, limestone, and shale bedrock depths ranging from less than 10 feet in the eastern portion of the site and approximately 150 feet below existing ground surface in the western portion of the Project Area.

#### **PROPOSED SCOPE OF WORK**

##### **Reconnaissance, Planning and Boring Layout**

The following will be conducted as part of this task:

1. A review of pertinent, readily available subsurface geotechnical information for the Site that is provided to the Geotechnical Engineer will be performed.
2. A site visit will be performed to lay out the borings and clear underground utilities at the boring locations. The landowner will be consulted to provide the geotechnical engineer with information and the locations of all private utilities at the site. The geotechnical engineer will be responsible for locating the boring, which should be surveyed and staked on the site prior to drilling.
3. The Ohio Utility Protection Service (OUPS) and Ohio Oil & Gas Producers Underground Protection Service (OGPUPS) will be notified a minimum of 48-hours prior to the commencement of drilling services.

##### **Drilling and Sampling**

After the geotechnical engineer has reviewed all available desktop information, they will determine the number of borings to be drilled at turbine locations. The borings will extend to the proposed depth or competent bedrock, whichever is encountered first.

For all borings, the following will be performed:

1. Split-barrel sampling of soil will be performed in accordance with ASTM International D 1586 for each boring in increments of 2.5 feet to the depth of 10 feet and at five-foot intervals below 10 feet to the depth of the borings. In all the borings, Standard Penetration Test (SPT) data will be developed and representative samples preserved.
2. It is anticipated that the drilling will be accessible with and performed by a truck-mounted drilling rig. Provisions shall be made by the Geotechnical Engineer based on the time of year the fieldwork will occur in using an ATV drill rig if the borings cannot be accessed with a truck-mounted drilling rig.
3. Water observations in the boreholes will be recorded during and at the completion of drilling.
4. All borings will be backfilled at the completion of drilling with bentonite chips and drill cuttings.

#### **Geotechnical Laboratory Testing**

A laboratory testing program will be established by the geotechnical engineer based on the observations made during the drilling activities and experience. The following laboratory tests shall be performed on samples retained during the drilling activities:

1. All samples will be classified in the laboratory based on the visual-manual examination (ASTM International D 2488) Soil Classification System and the laboratory test results. Formal boring logs will be prepared using the field logs and the laboratory classifications.
2. Laboratory testing will include moisture content, particle-size analyses, and Atterberg limits of a limited number of samples considered to be representative of the foundation materials encountered by the borings. Unconfined compression and consolidation tests will be performed if low strength and/or highly compressible cohesive soils are encountered as deemed necessary by the geotechnical engineer.
3. All laboratory testing will be performed in accordance with ASTM International or other specified standards.

#### **Geotechnical Exploration Report**

The geotechnical engineer will prepare a Geotechnical Exploration Report that will include the findings, conclusions and recommendations concerning proposed geotechnical related design-construction considerations and foundation design recommendations. The report shall also include an Appendix, which will include a boring location plan, a legend of the boring log terminology, the boring logs, and the results of any laboratory tests. Three (3) copies of the report will be presented by the Geotechnical Engineer.

Figure 1: 5-Mile Study Area

Figure 2: Facility Layout

## **EXECUTIVE SUMMARY**

This socioeconomic report is prepared in support of the proposed Republic Wind Farm (“the Facility”), a wind-powered electric generation facility in Sandusky and Seneca Counties of the State of Ohio (See Figure 1). The Facility will consist of 50 turbines, along with access roads, electric collection cables, a Facility substation, laydown yards for construction staging, an operations and maintenance (O&M) facility, and up to three meteorological towers. The Facility layout is illustrated in Figure 2. The energy generated at the Facility will deliver power to a single point of interconnection (POI) on the existing Fremont Center – Tiffin Center 138 kilovolt (kV) transmission line. The Facility will have an installed capacity of up to 198 megawatts (MW) and will deliver up to 640,000 megawatt-hours (MWh) of electrical power to the regional power grid. Construction is scheduled to begin in 2020.

The focus of this report is to assess the potential socioeconomic impacts of this Facility on local municipalities within a 5-mile radius from the Facility (“the Study Area”; see Figure 1), as well as across the State of Ohio. This involves a review of the past and current demographic and economic characteristics and trends in the Study Area, which includes 23 municipalities, and (where applicable) those of the greater region. The regional economy surrounding the Study Area is shaped in large part by the agricultural industries of Erie, Huron, Sandusky, and Seneca Counties as well as the metropolitan areas in northern Ohio and further afield. Potential impacts including those to employment, earnings, and overall economic output resulting from Facility construction and operation are assessed in light of socioeconomic conditions within the State of Ohio and the Study Area.

In short, the Republic Wind Farm is expected to produce a positive economic impact throughout the state and on the communities within the Study Area. Through lease payments to private landowners, short- and long-term job creation, and tax payments to each participating taxing jurisdiction, the Facility will supply a revenue stream to each of these jurisdictions without requiring significant services or expenditures on their behalf.

## **Part I: Introduction**

This socioeconomic report is prepared in support of the proposed Republic Wind Farm (“the Facility”), a wind-powered electric generation facility in Sandusky and Seneca Counties of the State of Ohio (See Figure 1). The Facility will consist of 50 turbines, along with access roads, electric collection cables, a Facility substation, laydown yards for construction staging, an operations and maintenance (O&M) facility, and up to three meteorological towers. The Facility layout is illustrated in Figure 2. The energy generated at the Facility will deliver power to a single point of interconnection (POI) on the existing Fremont Center – Tiffin Center 138 kilovolt (kV) transmission line. The Facility will have an installed capacity of up to 198 megawatts (MW) and will deliver up to 640,000 megawatt-hours (MWh) of electrical power to the regional power grid. Construction is scheduled to begin in early 2020.

This analysis examines estimated impacts to the state and local economy generated from the construction and operation of the Facility. It includes a review of existing demographic and economic characteristics in the area, as well as several trends affecting both. When such comparison is informative, state and federal demographic and economic data are also included. Unless noted otherwise, the Study Area for this report includes the following 23 municipalities in Erie, Huron, Sandusky, and Seneca Counties; all of which are found wholly or partially within a 5-mile radius of the Facility (the Study Area):

- Village of Green Springs\*
- Village of Republic
- City of Bellevue\*
- City of Clyde
- City of Tiffin
- Adams Township
- Ballville Township
- Bloom Township
- Clinton Township
- Green Creek Township
- Groton Township
- Hopewell Township
- Jackson Township
- Liberty Township
- Lyme Township
- Norwich Township
- Pleasant Township
- Reed Township
- Scipio Township
- Sherman Township
- Thompson Township
- Townsend Township
- Venice Township
- York Township

\*Note: The Village of Green Springs is geographically split between Sandusky and Seneca Counties. The City of Bellevue is geographically split between Erie, Huron, and Sandusky Counties

Part II of this report provides an examination of population trends within the State of Ohio and the Study Area, from 1990 through 2010, including projected population growth through 2030. In addition, Part II provides data regarding the civilian labor force for 2016 by state and county (latest data available). Part III reviews the types of potential impacts that could be experienced throughout the region, including those regarding housing demand, commercial and industrial employment, and transportation networks. Part IV describes the methods of analysis of potential economic benefits provided within this report, including an overview of the Job and Economic Development Impact (JEDI) Wind Model. This model was created by MRG & Associates, under contract with the National Renewable Energy Laboratory and is an industry standard for economic impact investigation. This is followed by the JEDI results (Part V), which describes the jobs created by the construction and operation of the Facility, as well as a summary of payments to landowners as a result of land leases for turbines. Part VI reviews potential impacts of the Facility from the perspective of local taxing jurisdictions. The findings of this report are summarized in Part VII, which is followed by a bibliography of cited sources in Part VIII.

## Part II: Socioeconomic Profile

### 1. Population trends

Census data reveals that these communities have experienced a varied history of small population growth and decline over the past two decades. The 2015 population for the State of Ohio and Erie, Huron, Sandusky, and Seneca Counties is shown in Table 1 below. Ohio showed an increase in population between 2000 and 2015, however, the counties in the study area each experienced an overall decrease of equal or higher magnitude between the same duration. Huron County experienced the smallest annual rate of population decrease (-0.1%) while Erie and Seneca Counties experienced the greatest overall decrease in population, at an annual rate of 0.3%. As indicated in Table 2, many of the local municipalities also demonstrate a general decrease in population from 2000 to 2015. Notable exceptions include more urban settings, such as the Village of Green Springs, which experienced a population increase at an annual rate of 3.0% over the same time span. The City of Tiffin is the largest of the 23 municipalities within a 5-mile radius of the proposed turbines and has experienced only a small decline of growth (-0.1% annual rate) (Table 2).

**Table 1: Population Trends**

County	2000 Pop.	2010 Pop.	2015 Pop.	Annual Rate of Change (2000-2015)	Est. 2030 Pop.	% Change 2015-2030	2017 Population Density (people per square mile)
Erie County	79,551	77,079	76,141	-0.3%	72,942	-4.2%	297.5
Huron County	59,487	59,626	58,937	-0.1%	58,394	-0.9%	119.4
Sandusky County	61,792	60,944	60,187	-0.2%	58,642	-2.6%	146.6
Seneca County	58,683	56,745	55,929	-0.3%	53,361	-4.6%	101.1
State of Ohio	11,353,140	11,536,504	11,575,977	0.1%	11,805,281	2.0%	285.3

Source: U.S. Census Bureau, 2000 and 2010 Decennial Census and American Community Survey 5-Year Estimates 2011-2015. Population densities from American Community Survey 1- Year Estimates 2017. Projections derived from each jurisdiction's constant annual rate of change between 2000-2015.

For the purposes of this report, the trends experienced by each community from 2000 to 2015 are expected to continue regardless of whether the proposed Facility is built. Over the next decade, the total population within the Study Area is projected to increase by 1.3% from 2015 to 2025, from 70,791 to 71,702; mirroring the projected statewide increase of 1.4% during the same time span. Meanwhile, county population projections are expected to decline between the same time span. Seneca County is projected to experience the greatest decrease in population (-3.4%) from 2010-2025, while Huron County is projected to experience only a -0.7% decline in population during the same time span (see Table 1).

**Table 2: Population Projections**

Jurisdiction within 5-Miles Radius of Facility	2000 Pop.	2010 Pop.	2015 Pop.	Annual Rate of Change (2000-2015)	Est. 2030 Pop.	% Change 2015-2030	2016 Population Density (people per square mile)
City of Bellevue	8,193	8,282	8,109	-0.1%	8,026	-1.0%	1,335
City of Clyde	6,064	6,325	6,305	0.3%	6,560	4.0%	1,202.2
City of Tiffin	18,135	17,963	17,793	-0.1%	17,460	-1.9%	2,577.7
Adams Township	1,337	1,320	1,435	0.5%	1,544	7.6%	106.9
Ballville Township	6,395	5,985	5,911	-0.5%	5,479	-7.3%	175.1
Bloom Township	1,937	1,799	1,591	-1.2%	1,329	-16.4%	43.3

<sup>1</sup> Denotes that entity did not exist as currently structured as of April 1, 2010, Census Day, % change is calculated from 2010-2015

<sup>2</sup> Totals calculated by formula, may reflect rounding errors

Although construction employment related to the construction of the Facility will be substantial, this employment is relatively short term and is not expected to result in the permanent relocation of construction workers to the area; therefore, the Facility is not anticipated to generate significant population growth within the Study Area. The number of potential short- and long-term employment opportunities associated with the construction and operation of the Facility is discussed in further detail below.

## 2. Employment statistics

Table 3 illustrates the size of the local labor force in counties located either wholly or partially within 5 miles of the proposed Facility, as well as the broader State of Ohio. The total annual unemployment rate for Sandusky and Seneca Counties has been relatively consistent with that of the state over the last two years; however, the total annual unemployment rate for Erie and Huron Counties has been slightly higher compared to that of the state. Annual average unemployment rates have decreased both statewide and countywide from 2014 to 2016. Table 4a through Table 4e illustrates employment figures in the State of Ohio and Erie, Huron, Sandusky, and Seneca Counties broken down by sector for 2015.

**Table 3: Local Labor Force and Unemployment**

Place	Labor Force	Employed	Unemployed	Unemployment rate	Unemployment rate, 2015 (annual)	Unemployment rate, 2014 (annual)
Erie County	37,127	35,100	2,027	5.5%	5.5%	6.4%
Huron County	27,864	26,063	1,801	6.5%	6.6%	8.0%
Sandusky County	30,908	29,465	1,443	4.7%	4.8%	5.7%
Seneca County	27,164	25,855	1,309	4.8%	4.8%	5.7%
State of Ohio	5,713,088	5,430,790	282,298	4.9%	4.9%	5.8%

Note: Not Seasonally Adjusted; Source: U.S. Bureau of Labor Statistics, 2016.

**Table 4a: Employment and Payroll by NAICS Sector in the State of Ohio**

NAICS code description	Paid employees for pay period including March 12, 2015	First-quarter payroll (\$1,000)	Annual payroll (\$1,000)	Total establishments
Total for all sectors	4,719,985	52,632,423	213,161,303	251,668

## **Part III: Regional Development Impacts**

The regional economy surrounding the Study Area is shaped in large part by the agricultural industries of Erie, Huron, Sandusky, and Seneca Counties. While the Study Area is predominantly rural, the City of Toledo (west of the Study Area) and the City of Cleveland (east of the Study Area), both significant metropolitan regions, are each in relative proximity to the Study Area. Erie, Huron, Sandusky, and Seneca Counties are primarily agricultural in nature. The regional context for the development of this Facility is discussed in further detail below, concentrating on three primary components: housing, commercial and industrial development, and transportation. In addition, the compatibility of the proposed Facility with regional developmental goals and plans is reviewed.

### **1. Housing**

As with all sectors of the economy, the housing market throughout the region has felt the impact of population loss. Owner-occupied vacancy rates in Erie, Huron, Sandusky, and Seneca Counties (ranging from 2.0% to 2.3%) are slightly higher than the statewide average of 1.9%. The rental vacancy rate in Huron County (11.7%), Sandusky County (9.7%), and Seneca County (7.1%) is substantially higher than the statewide average of 6.5%, while the rental vacancy rate in Erie County is only 0.1% higher than the statewide average.

Erie, Huron, Sandusky, and Seneca Counties feature a median monthly gross rent level of \$707, \$630, \$634, \$645, respectively, all of which is below the statewide average of \$730/month. Each county has a lower than statewide percentage of households whose rent accounts for more than 35% of their household income. In addition, the median housing values of Huron, Sandusky, and Seneca Counties are below the statewide average of \$129,900, while Erie County's median housing value (\$131,400) is slightly above the statewide average.

It is estimated that 13,631 housing units within Erie, Huron, Sandusky, and Seneca Counties are currently vacant. Given these figures, in addition to the population projections discussed in Part II of this report, it is not expected that the development of the Facility will have a significant impact on the regional housing market. While the Facility development may not represent a widespread boom for rental property owners, it is worth noting that the availability of vacant rental housing also indicates that the Facility should not have a destabilizing effect on current renters.

**Table 5: Study Area Housing Characteristics**

Municipality/County/State	Total housing units	Occupied units	Vacant units	Vacancy rate		Median housing value of owner-occupied units	Median gross rent (monthly)	% of households with gross rent > 35% of household income
				Home - owner	Rental			
Village of Green Springs	265	256	9	0.0%	0.0%	\$82,700	\$835	52.9%

Ohio Statewide	5,140,902	4,585,084	555,818	1.9%	6.5%	\$129,900	\$730	40.3%

Source: U.S. Census Bureau, American Community Survey 5-Year Estimates 2011-2015. (x) = data unavailable

## 2. Commercial and Industrial Development

The diversification of Ohio's energy portfolio will have significant and positive economic impacts beyond a reduced dependence on coal imported from outside of the state. The Environment Ohio Research & Policy Center estimated that if the State of Ohio increased wind power production to 20% of the state's total energy portfolio by 2020, such development would create 3,100 permanent, full-time positions within the state, and result in cumulative wages totaling \$3.7 billion. This same analysis estimated that such a commitment would result in an increase in gross state product of approximately \$8.2 billion by 2020 (Environment Ohio, 2007).

These impacts are principally due to the impact of wind energy development on the manufacturing sector. The State of Ohio is uniquely positioned to take advantage of advanced manufacturing opportunities for the development and distribution of wind power technology, according to the Renewable Energy Policy Project's (2004) report, "Wind Turbine Development: Location of Manufacturing Activity." This analysis estimates that if the United States were to invest \$50 billion into 50,000 MW of new wind power production, Ohio manufacturers could stand to create 11,688 jobs in wind turbine and related manufacturing, accounting for 1.95% of the total investment; by way of comparison, the American Wind Energy Association estimates that the State of Ohio alone has enough wind resources to generate nearly 359 MW at 80m hub height and 110,439 MW at 110m hub height of onshore wind energy (AWEA, 2015).

The Environmental Law & Policy Center estimated that the State of Ohio is currently home to 106 wind power supply chain businesses, providing 1,000 to 2,000 jobs throughout the state (ELPC, 2011). Wind energy technology manufacturing opportunities include rotors, controls, drive trains, generators, and towers. Several of these manufacturers and other wind power-related businesses are located in the Greater Cleveland Region (AWEA, 2015).

Specific short- and long-term economic impacts of this Facility on commercial and industrial development throughout the region are described in further detail in Part V of this report.

## 3. Transportation

The region surrounding the Facility features numerous Interstates, U.S., and State highways, as well as county and local roadway networks, in addition to freight rail lines and small airports. These facilities are described in further detail below. The main transportation route to the Facility is I-80/90 (Ohio Turnpike), which runs just north of the 5-mile Study Area. U.S. Route 20 (north) and State Route 4 (east) run adjacent to the Facility. State Routes 53 and 269 provide direct access into the Facility. These and other primary routes facilitate transportation between the Facility and the surrounding metropolitan areas.

Workers coming to and from the site will most likely enter via State Route 4 or 20 from I-80/90. Construction traffic bound for the substations will likely use State Route 53 as the primary route, while traffic bound for the Operations and Maintenance area will most likely use U.S. Route 20 as the primary route. The proposed Facility is not expected to cause any substantial disruption to major transportation corridors serving the Study Area.

Freight rail lines connect several of the municipalities throughout the Study Area. CSX and Norfolk Southern operate the majority of Ohio's freight rail system, although smaller operators such as Ashland Railway, Northern Ohio and Western Railway, and Wheeling and Lake Erie Railway also operate in the area. Study Area municipalities connected to freight rail lines include the Cities of Bellevue, Clyde, and Tiffin, the Townships of Adams, Ballville, Bloom, Clinton, Green Creek, Groton, Hopewell, Jackson, Liberty, Lyme, Norwich, Pleasant, Reed, Scipio, Thompson, Venice, and York, and the Village of Green Springs. The rail system may be used for the transportation of a very small number of turbine component and equipment suppliers, but the Applicant does not anticipate making any modifications to the system.

The Study Area is also in proximity to the Huron County Airport, the Sandusky County Regional Airport, the Seneca County Airport, the Bandit Field Airport, the Fremont Airport, the Fostoria Airport, the Weiker Airport, and the Willard Airport. Construction and operation of the Facility will be designed according to Federal Aviation Administration (FAA) standards and are not expected to result in any adverse impacts to the regional air transportation network. The Applicant will file a notice of proposed construction or alteration (Form 7460-1) with the FAA to confirm the structure will not result in a substantial adverse impact.

#### 4. Local and Regional Plan Compatibility

Several of the municipalities within the five-mile study area have adopted comprehensive land use plans, strategic downtown plans, and/or economic development plans. Each of these are summarized below:

- City of Bellevue Vision 2025 Comprehensive Master Plan: This plan, adopted in 2005 by the Bellevue City Council, identifies the need for a 20-year vision, in which the issues, concerns, goals, and priorities of the community are addressed through civic engagement. High-paying job creation in the manufacturing sector, as well as the retention of existing jobs and the preservation of existing farming operations are goals and issues presented in the plan (City of Bellevue, 2005). In terms of economic development, the Facility offers an opportunity for the use of local goods and services, including but not limited to labor, equipment, and maintenance. In addition, the payments associated with land leases provide additional income for landowners, including agricultural producers, and in doing so, improves the economic conditions for existing farming practices.

- 2016 City of Tiffin Downtown Strategic Growth and Development Plan: This strategic plan complements the previously-created 2010 Strategic Downtown Tiffin Plan, which “creates urban design solutions with policy recommendations to invigorate the urban core and community as a whole, with a revitalized and enhanced downtown” (City of Tiffin, 2010). Guided by revitalization principles for downtown areas and the local economy, the plan recommends that infill development utilize alternative energy when possible and support opportunities to develop local green tech industries (City of Tiffin, 2016). While the Facility does not directly impact the downtown area, it is compatible with the strategic plan through its diversification of the region’s energy resource portfolio, adding resilience and reliability to the supply of energy resources to local businesses. The Facility also offers an opportunity for the use of local goods and services, including those provided by businesses located in the downtown area.
- 1995 Erie County Comprehensive Development Plan: This plan “determines the immediate and future needs of the community and provides ways to allow the County to guide appropriate land uses to the most suited areas for that kind of development” (Erie County, 1995). By analyzing the existing conditions and growth trends of the County, along with issues facing the region, the plan identifies goals for future land use and policy making. The Facility is compatible with the Plan’s goal to “promote community development through the improvement of infrastructure that meets development demands”.
- 2017 Huron County Comprehensive Land Use Plan: Originally developed in 2007 and last revised in 2017, the Huron County Commissioners, the Huron County Comprehensive plan aims to manage future growth within the County to cohesively guide development patterns over the next thirty years. A key goal is to promote Huron County as a development destination and to retain and expand existing businesses (Huron County, 2017). The Facility is compatible with this goal due to the positive impacts it will create for the local economy.
- 2013 Sandusky County Comprehensive Plan: This plan is an update to the 2003 Comprehensive Plan and is intended to be long-range plan used to guide growth and development using current existing condition, along with updated trends and priority project. A major goal of the plan is to facilitate the economic health and growth of the County and its municipalities by expanding on the tax and employment base. Furthermore, the plan “promotes and facilitates the proper placement and provision of energy infrastructure components throughout the County, including but not limited to wind farms and solar arrays” (Sandusky County, 2013). The Facility is compatible with these goals, specifically the placement and provision of alternative energy infrastructure.

- 2011 Seneca County Comprehensive Economic Development Strategy: The plan is intended to position Seneca County as a “redevelopment area,” as defined by the EDA, and thus to make its political subdivisions eligible to apply from the EDA Public Works and other programs. As specified by the plan, “the assumptions, goals, and strategies laid out in the plan create a blueprint for the County’s overall economic development and a summary of what is considered the most effective and proactive, targeted strategy to improve the economic position and climate of Seneca County” (Seneca County, 2011). The plan also specifies that the County recently approved a resolution to make Seneca County an “Alternative Energy Zone”, making it eligible for state tax incentives. The Facility is compatible with the plan’s priority action to improve the local economy and implement alternative energy.

The Facility is located in an area that is largely rural in nature with a majority of impacts from the Facility construction and operation occurring on land used for agriculture. The economic benefits of the turbines for local agriculturalists, as well as their overall compatibility with farming practices, will support and aid in the preservation of local farming operations. Furthermore, the jobs and economic development created by Facility may help to create and retain existing local employment opportunities. Therefore, the development of this Facility is compatible with the goals and strategies of existing local and regional plans.

##### 5. Concurrent or secondary uses

Facility components will be located on portions of leased land with existing rural residential or agricultural uses. These existing uses are expected to continue throughout the lifetime of the Facility.

## Part IV: Assessing Job and Economic Development Impacts

### 1. Jobs and Economic Development Impact (JEDI) Model

The proposed Republic Wind Farm is anticipated to have local and statewide economic benefits. Wind power development, like other commercial development projects, can expand the local, regional, and statewide economies through both direct and indirect means. Income generated from direct employment during the construction and operation phases of the wind farm is used to purchase local goods and services, creating a ripple effect throughout the state. The Job and Economic Development Impact (JEDI) Wind model allows users to estimate exactly that; the jobs and the economic development impacts from wind power generation projects for both the construction and operation phases of the proposed Facility (NREL 2017). These economic development impacts, categorized by the levels of impact and indicators described below, include onsite jobs and earnings, economic output from these onsite earnings, local revenue/supply chain jobs and earnings, economic output from these local revenue/supply chain earnings, induced jobs and earnings, and economic output from these induced jobs and earnings. The JEDI model was created by the National Renewable Energy Laboratory (NREL), a national laboratory of the United States Department of Energy. It then calculates the aforementioned indicators for each level of impact using project-specific data provided by the Applicant and geographically-defined multipliers. These multipliers are produced by IMPLAN Group, LLC using a software/database system called IMPLAN (IMpact analysis for PLANing), a widely-used and widely-accepted general input-output modeling software and data system that tracks unique industry groups in various levels of the regional data (IMPLAN Group, 2018).

Using the JEDI wind model, this report analyzes three levels of impact that the proposed Facility may have on the economy:

**On-site labor impacts:** These are the direct impacts experienced by the companies/individuals residing in the State of Ohio engaged in the onsite construction and operation of the Facility. These values represent expenditure of dollars on labor (wages, salaries and associated expenses) by Facility onsite construction personnel as well as operation and maintenance (O&M) personnel. On-site labor impacts do not reflect material expenditures. Most other input-output models consider this level as “direct impacts”, referring to changes in jobs, economic activity and earnings associated with the immediate impacts created by the investment, which would include the equipment installed onsite, the concrete used onsite, etc. However, the immediate economic impacts of the physical items used onsite, normally included in direct impacts, typically occur at some geographic distance from the project itself. Because of JEDI’s focus on the local impacts of a Facility, only the labor associated with the on-site location of the Facility (Construction and Construction-Related Services) is counted at this level.

**Local revenue and supply chain impacts:** These impacts measure the estimated increase in demand for goods and services in industry sectors that supply or otherwise support the companies engaged in construction and operation (also known as “backward-linked” industries). These measures account for the demand for goods and services such as turbine components, project analysis, legal services, financing, insurance, etc. Most other input-output models consider this level as “indirect impacts”, referring to economic impacts associated with linked sectors in the economy that are upstream of the direct impacts, such as suppliers of hardware used to make the equipment installed onsite or the concrete used onsite. However, because of JEDI’s focus on the local impacts of the Facility, labor for components of this Facility (e.g. turbine manufacturers) occurring at off-site locations is also counted in this level as a local revenue and supply chain impact.

**Induced impacts:** Induced impacts measure the estimated effect of increased household income resulting from the project. Induced impacts reflect the reinvestment of earned wages, as measured throughout the first two levels of economic impact. This reinvestment can occur anywhere within the local, regional, or state economy, on household goods, entertainment, food, clothing, transportation, etc.

Each of these three levels of impact can be measured in terms of three indicators: jobs (as expressed through the increase in employment demand), the amount of money earned through those jobs, and the overall economic output associated with each level of economic impact. These indicators are described in further detail:

**Jobs:** Jobs refer to the increase in employment demand because of facility development. These positions are measured across each level of impact, so that they capture the estimated number of jobs on site, in supporting industries, and in the businesses, that benefit from household spending. For the purposes of this analysis, this term refers to the total number of year-long full-time equivalent (FTE) positions created by the Facility. Persons employed for less than full time or less than a full year are included in this total, each representing a fraction of a FTE position (e.g. a half-time, year-round position is 0.5 FTE).

**Earnings:** This measures the wages and salary compensation paid to the employees described above.

**Output:** Output refers to the value of industry production in the state economy, across all appropriate sectors, associated with each level of impact. For the manufacturing sector, output is calculated by total sales plus or minus changes in inventory. For the retail sector, output is equal to gross profit margin. For the service sector, it is equal to sales volume. For example, output would include the profits incurred by those businesses that sell electrical transmission line, concrete, or motor vehicle fuel to the Applicant.

## 2. Methodology

Calculating the number of jobs and economic output from a proposed facility using the JEDI model is a two-step process. The first step requires a limited amount of facility-specific data inputs (such as year of construction, size of Facility, turbine size and location). For the analysis, the following data were used as facility-specific modeling inputs.

- Location: Ohio
- Year of Construction: 2020
- Total Project Nameplate Capacity: 200 MW
- Number of Turbines: 47
- Average Turbine Capacity: 4.255 MW
- Money Value (Dollar Year): 2018

Note that the Applicant presents a turbine layout of up to 50 turbines for permitting purposes, each with a nameplate capacity rating of 4.2 to 4.5 megawatts (MW). However, the total generating capacity of the Facility will not exceed 200 MW. Therefore, the number of turbines to be constructed will range between 44 and 47, depending on the model of turbine selected. Since no more than 47 turbines will ultimately be constructed, this socioeconomic report analyzes the total number of positive jobs and economic impacts produced by a 47 turbine Facility rather than a 50 turbine Facility, to avoid overestimating the Facility's economic benefits.

Using this Facility-specific data, the JEDI model then creates a list of default values, which includes project cost values, default financial parameter values, default tax values, default lease payment values, and default local share of spending values. These default values are derived from 10 years of research by NREL, and stem from various sources, including interviews and surveys from leading project owners, developers, engineering and design firms, and construction firms active in the wind energy sector. The version of the model (W9.14.18) used for the job and economic impact analysis presented here used the most currently available (2016) multiplier data specific to Ohio to estimate potential impacts on a statewide basis. The second step of the JEDI model methodology requires the review, and if warranted, the customization of default project cost values and financial parameter values to more reasonable estimates. The Applicant reviewed the default project cost values subtotalized by each of the following categories in the JEDI model: Equipment during Construction, Balance of Plant Construction, Labor during Operation & Maintenance, Materials and Services during Operation & Maintenance, Financial Parameters, Tax Parameters, Land Lease Parameters and Payroll Parameters. The Applicant reviewed the default values in November 2018 and determined whether they were appropriate for the project under review. As a result of that review, adjustments were made to specific default values (see Table 6). The remaining JEDI default values were reviewed and determined to be reasonable estimates based on the Applicant's previous experience in wind energy development.

**Table 6: Adjustments Made to Default JEDI Model Costs**

JEDI Cost Items (Annual Estimates)	Default Value	Adjusted Value	Change
Construction Equipment Costs	\$241,413,521	\$ [REDACTED]	\$ [REDACTED]
Construction Materials Costs	\$50,587,878	\$ [REDACTED]	\$ [REDACTED]
Construction Labor Total Costs	\$20,956,908	\$ [REDACTED]	\$ [REDACTED]
Development Costs	\$9,004,072	\$ [REDACTED]	\$ [REDACTED]
Sales Tax for Construction Materials and Equipment	\$15,304,784	\$ [REDACTED]	\$ [REDACTED]
Equity Financing Repayment Term	10 years	\$ [REDACTED]	\$ [REDACTED]
Taxes Per MW	\$0	\$ [REDACTED]	\$ [REDACTED]
Land Lease (Total Cost)	\$600,000	\$ [REDACTED]	\$ [REDACTED]

## Part V: Job and Economic Development Impacts on the Statewide Economy

An economic impact analysis was performed for the Republic Wind Farm (the Facility) to be constructed in 2020 with a rated capacity of 200 MW and an assumed 47 turbines, sized at 4.255 MW. The analysis presented here used the most currently available (2016) multiplier data specific to Ohio to estimate potential impacts on a statewide basis. The results of this analysis, estimated for both the construction and operation phases of the proposed Facility, are illustrated in Table 7 and summarized in the narrative that follows.

**Table 7: Summary Results of Job and Economic Impact Analysis**

	Jobs	Earnings (Millions)	Output (Millions)
<b>Construction</b>			
Project Development and Onsite Labor Total	181	\$10.5	\$10.6
Construction & Interconnection Labor	180	\$10.3	-
Construction Related Services	1	\$0.1	-
Turbine & Supply Chain Impacts	403	\$22.7	\$75.7
Induced Impacts	169	\$8.3	\$25.9
<b>Total Impacts</b>	<b>753</b>	<b>\$41.4</b>	<b>\$112.2</b>
<b>Annual Operation</b>			
Onsite Labor Impacts	10	\$0.6	\$0.6
Local Revenue and Supply Chain Impacts	22	\$1.2	\$3.8
Induced Impacts	9	\$0.5	\$1.5
<b>Total Impacts</b>	<b>41</b>	<b>\$2.3</b>	<b>\$5.9</b>

Source: NREL JEDI Model (version W9.14.18) (USDOE NREL, 2018)

Notes: Earnings and Output values are millions of dollars in 2018 dollars. Totals may not add up due to independent rounding. Results are based on model default values.

Demand for new jobs associated with the Facility will be created during both the initial construction period and the years following construction, in which the Facility is in operation. The money injected into the statewide economy through the creation of these jobs will have long-term, positive impacts on individuals and businesses in Ohio as it ripples through the economy.

#### 1. Statewide Job and Economic Development Impact: Construction

Based upon JEDI model computations, it is anticipated that construction of the proposed Facility will directly generate employment of an estimated 181 FTE on-site construction and project development positions for Ohio residents, which will be for Construction and Interconnection Labor and Construction Related Services. The JEDI model estimates in a total of \$10.3 million for annual earnings of the 180 on-site construction jobs. Turbine manufacturing and supply chain industries could in turn generate an additional 403 jobs across the State of Ohio over the course of Facility construction. In addition, Facility construction could induce demand for 169 jobs statewide through the spending of additional household income. Based on the results of the model, the total impact of potentially 753 new jobs could result in up to \$41.4 million of earnings, assuming a 2018 construction schedule and wage rates consistent with statewide averages. Facility construction labor wages for similar construction positions within the North Northeastern Ohio Non-Metropolitan Area (which includes Seneca and Sandusky Counties) range from an average of \$18.18 per hour for Construction Laborers, \$24.09 for Electricians, and \$50.14 for Construction Managers (Bureau of Labor Statistics, 2016). Local, regional, and statewide employment during the construction phase will primarily benefit those in the construction trades, including equipment operators, truck drivers, laborers, and electricians. Facility construction will also require workers with specialized skills, such as crane operators, turbine assemblers, specialized excavators, and high voltage electrical workers. It is anticipated that many of the highly-specialized workers will come from outside the area and will remain only for the duration of construction.

In addition to jobs and earnings, the construction of the Facility is expected to have a positive impact on statewide economic output, a measurement of the value of goods and services produced and sold by backward-linked industries. As described in the definition above, output provides a general measurement of the amount of profit earned by manufacturers, retailers, and service providers connected to a given project. Based on the results of the model, the value of economic output associated with Facility construction is estimated to be \$112.2 million. Between workers' additional household income and industries' increased production, the impacts associated with the Facility are likely to be experienced throughout many different sectors of the statewide economy. Pursuant to Section 5727.75 of the Ohio Revised Code (ORC), the Facility may qualify for tax incentives based on the degree to which it employs in-state construction labor (see Part VI). At the time of the publication of this report, it is not yet known what portion of construction labor will be Ohio-domiciled.

## 2. Statewide Job and Economic Development Impact: Operations and Management

Based upon JEDI model computations, the operation and maintenance of the proposed Facility is estimated to generate 10 full-time equivalent onsite jobs with combined estimated annual earnings of approximately \$0.6 million. These 10 jobs are anticipated to be comprised of Project Management, Technician, and Administrative personnel. Projected wage rates are projected to be consistent with statewide averages which are estimated to be \$17.32 per hour for Payroll and Timekeeping Clerks, \$21.78 per hour for Mechanical Engineering Technicians, and, \$45.66 for General and Operations Managers (Bureau of Labor Statistics, 2016). These 10 full-time local jobs generated by the wind energy facility comprise the Facility's direct long-term employment impact.

Operations and maintenance should also generate new jobs in other sectors of the economy through supply chain impacts and the expenditure of new and/or increased household earnings. Increased employment demand throughout the supply chain is estimated to result in approximately 22 jobs with annual earnings of approximately \$1.2 million. In addition, it is estimated that 9 jobs with associated annual earnings of \$0.5 million will be induced through the increased household spending associated with Facility operations. In total, while in operation, this Facility is estimated to generate demand for 41 jobs per year with annual earnings of approximately \$2.3 million. Total economic output could also increase by an estimated \$5.9 million as a result of Facility operations and maintenance.

## 3. Land Lease Payments

Operation of the Project will result in payment to local landowners in association with the lease agreements executed to host Project components. These annual lease and easement payments will offer direct benefits to participating landowners, which will be in addition to any income generated from the surrounding land use (e.g. agricultural production). The Applicant estimates that these payments will total approximately \$1,300,000 million on an annual basis each year the Project is in operation, although this value is contingent upon project details still in development (e.g., turbine choice and layout). The Project will also generate lease payments during the construction phase; while the value is currently unknown, the lease payments will have a beneficial impact on the local economy during construction. These lease payments will have a positive impact on the region, to the extent that landowners will spend their revenue locally.

## Part VI: Local Tax Revenues

### 1. Legislative Context

Wind energy projects in the State of Ohio can be exempted from tangible personal property and real property tax payments if they meet certain conditions. These conditions are enumerated in Section 5727.75 of the ORC. Operators of these exempted projects, known as qualified energy projects (QEP), are instead required to make annual payments in lieu of taxes (PILOT). In order to be certified as a QEP by the state, a project must meet all of the following criteria:

- an application for certification of the energy project as a QEP that complies with the requirements under Section 5727.75 of the ORC and Chapter 122:23-1 of the OAC must be submitted to the director of the Ohio Development Services Agency (ODSA) on or before December 31, 2020;
- an application under Section 4906.20 of the ORC must be submitted to the Ohio Power Siting Board (OPSB) on or before December 31, 2020;
- the county commissioners of a county in which property of the project is located must have adopted a resolution approving the application submitted to ODSA or the county commissioners must pass a resolution declaring the county an alternative energy zone (AEZ);
- at least 50% of the full-time equivalent construction and installation employees, as defined in Section 5727.75 of the ORC, must be Ohio-domiciled; and
- construction (defined as either the date the application for a certificate is filed with OPSB or the date the contract for construction or installation is entered into, whichever is earlier) must begin by January 1, 2021.

If an applicant is granted exemption from taxation for any of the tax years 2011 through 2021, the QEP will be exempt from taxation for tax year 2022 and all ensuing years if the property was placed into service before January 1, 2022. The amount of PILOT to be paid annually to the county treasurer, ranging from \$6,000 and \$8,000, is assessed per megawatt (MW) of nameplate capacity, with the rate dependent on the percentage of construction/installation employees who are domiciled in Ohio. The PILOT would be: \$6,000 per MW, if during construction the project employs 75% or more Ohio-domiciled employees; \$7,000 per MW, if during construction the project employs 60% or more Ohio-domiciled employees; and \$8,000 per MW, if during construction the project employs the minimum requirement of 50% or more Ohio-domiciled employees (Table 8). County commissioners may require an additional service payment, as long as the total of the additional payment and the PILOT do not exceed \$9,000 per MW.

**Table 8: Service Payment per Megawatt Schedule**

Annual Service Payment per Megawatt of Nameplate Capacity	Ratio of Ohio-Domiciled Full-Time Equivalent Employees
\$6,000	75% or More
\$7,000	60% to 74%
\$8,000	50% to 59%

## 2. Estimated Payments In Lieu Of Taxes

Turbines for the Republic Wind Farm are anticipated to be located in a total of five municipalities (Adams, Pleasant, Reed, Scipio, and Thompson Townships) in Seneca County and one municipality (York Township) in Sandusky County, along with four school districts (Bellevue City School District, Clyde-Green Springs Exempted Village School District, Old Fort Local School District, Seneca East Local School District). Table 9 displays the total estimated PILOT revenues to be distributed throughout all taxing jurisdictions under the four scenarios identified in the payment schedule in Section 5727.75 of the ORC.

**Table 9: Estimated Total PILOT Revenue**

Total Facility capacity (MW)	PILOT at \$6,000/MW	PILOT at \$7,000/MW	PILOT at \$8,000/MW	PILOT at \$9,000/MW
200	\$1,200,000	\$1,400,000	\$1,600,000	\$1,800,000

## **Part VII: Conclusion**

The socioeconomic effects of the Republic Wind Farm, when assessed in light of regional and local economic trends, will have a positive impact on the communities within the Study Area and across the State of Ohio. Lease payments, short- and long-term job creation, and PILOT revenues will benefit private landowners, businesses, and taxing jurisdictions. The Facility is not expected to generate significant expenditures on behalf of these beneficiaries; therefore, it will have a positive impact on the social and economic conditions of these communities and across Ohio.

### **1. Total Statewide Economic Benefit**

The construction of the Republic Wind Farm is expected to produce \$41.1 million in employment earnings and \$112.2 million in total economic output. Subsequently, each year the Facility is operational it is expected to generate approximately \$2.3 million in earnings and \$5.9 million in total economic output.

### **2. Statewide Employment Benefits**

During the construction period, the Facility is expected to support demand for a total of 753 onsite, supply chain, and induced employment positions. It is expected to support a total of 41 positions during each year of its operation.

### **3. Land Lease Revenues**

The development of the Facility will result in \$ [REDACTED] in annual lease payments made to participating landowners.

### **4. Property Tax Revenues**

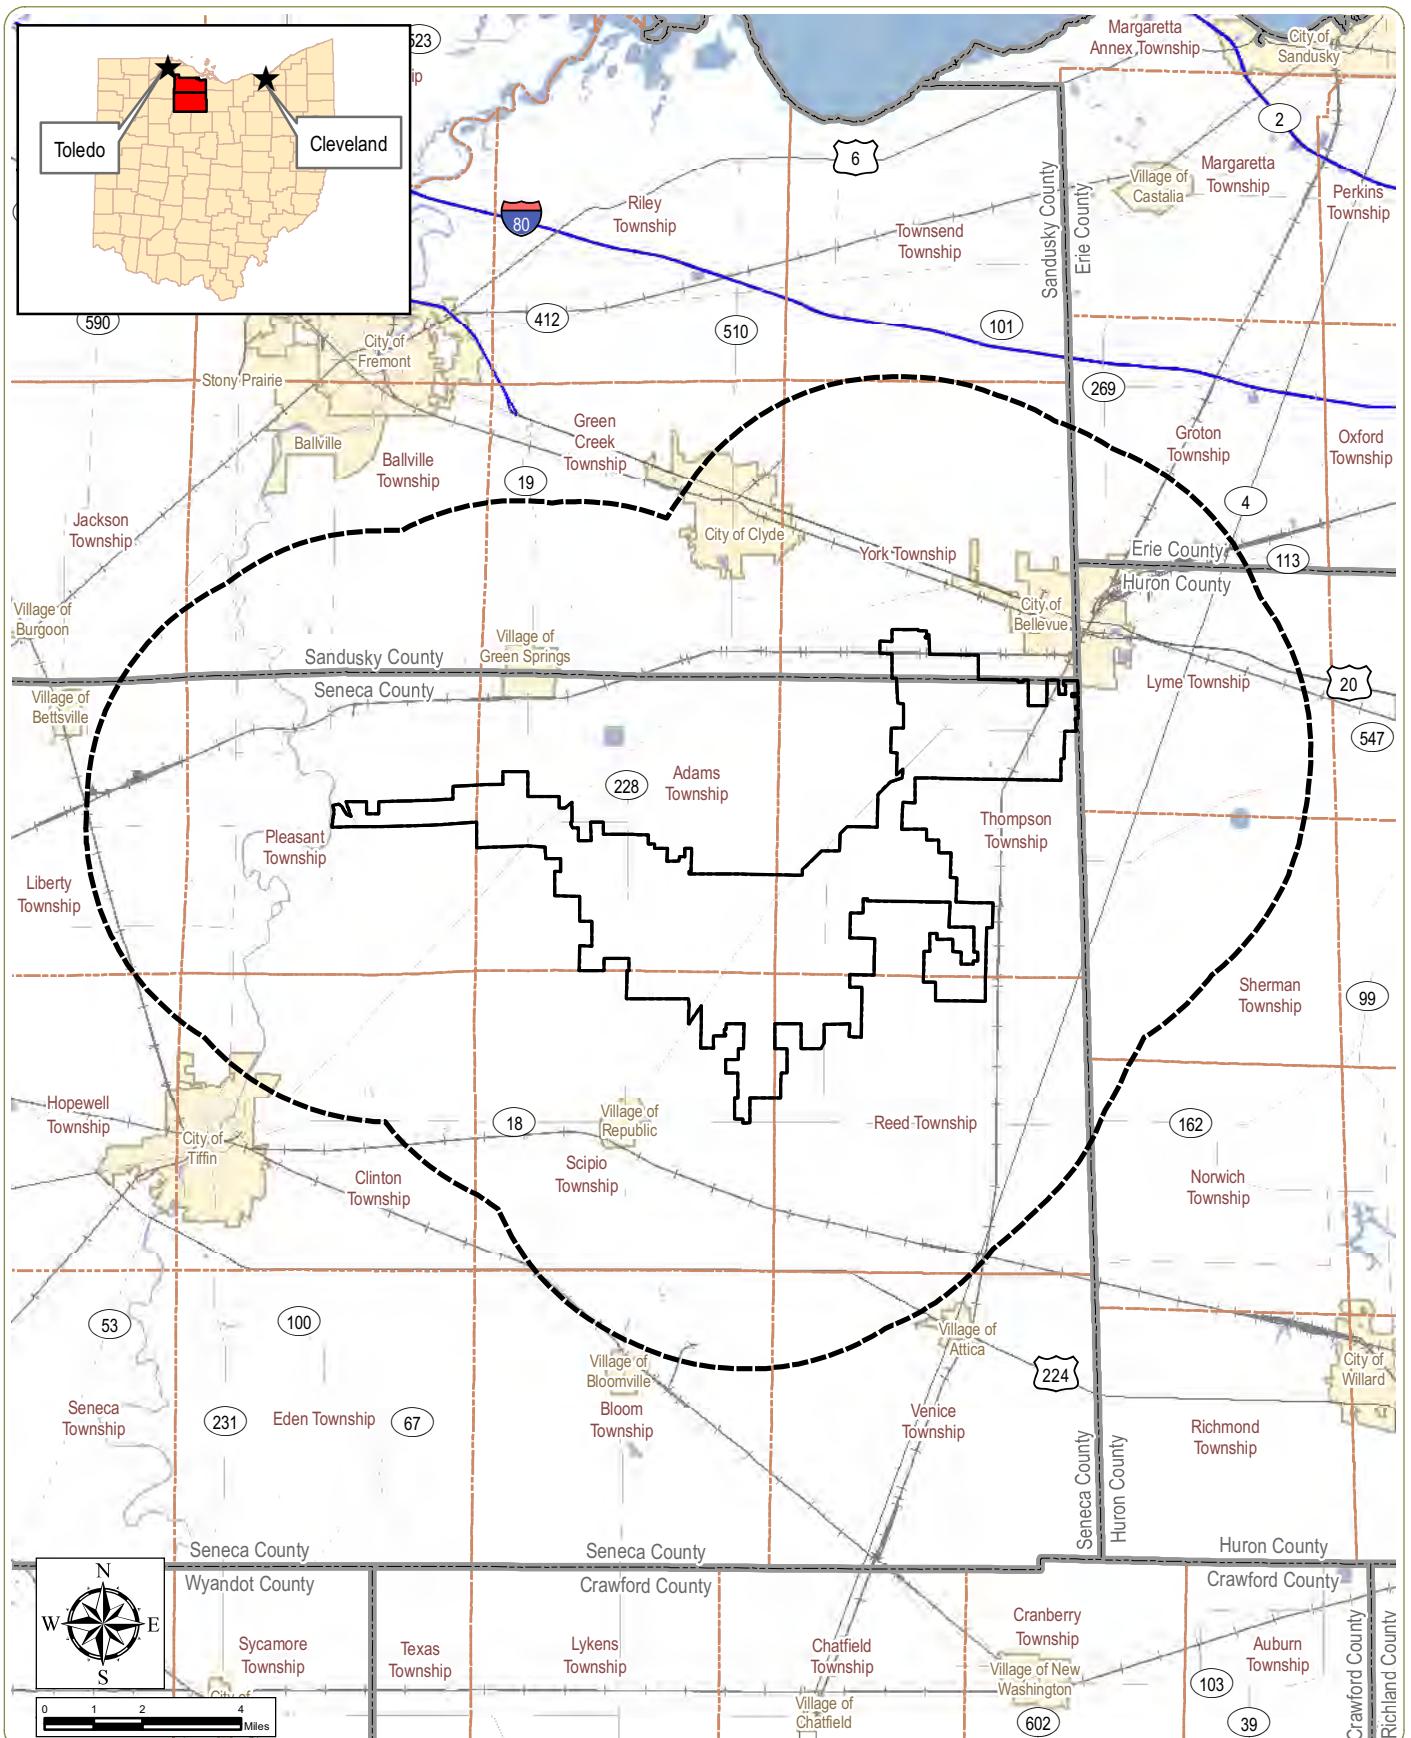

Construction of the proposed Republic Wind Farm will increase local government revenues through payments in lieu of taxes (PILOTs). Though the agreements outlining these payments are not yet finalized, it is estimated that annual PILOT revenues could amount to approximately \$1.2 million to \$1.8 million to be distributed to local taxing jurisdictions.

## **1.0 INTRODUCTION**

---

Apex Clean Energy is proposing the Republic Wind project in an area straddling the border between Seneca County and Sandusky County, Ohio between the towns of Republic and Bellevue. A previous noise assessment was published for this project by RSG (*Noise Impact Assessment for Republic Wind*, December 22, 2017) with a 58-turbine array. The array summarized in this current report has up to 50 wind turbines, with one spare location, modeled with three turbine model options. The current array is being presented as an alternative and does not replace the previous array.

As part of the Ohio Power Siting Board (OPSB) permitting process, Apex Clean Energy retained RSG to conduct a pre-construction noise assessment. This assessment includes both long-term background sound monitoring and computer sound propagation modeling of the proposed turbines.

This report includes:

- A project description;
- A summary of sound level limits applicable to the project;
- Background sound level monitoring procedures and results;
- Discussion of acoustical concerns particular to wind turbine noise;
- Sound propagation modeling procedures and results;
- Construction noise modeling;
- Discussion; and
- Conclusions.

## 2.0 PROJECT DESCRIPTION

---

Republic Wind is proposed to span Seneca and Sandusky Counties in Ohio. The project rights have been acquired by Apex Clean Energy.

The project covers approximately 15,000 acres, with up to 58 wind turbine locations and a total project output of at least 200 MW. A map showing the project area is shown in Figure 1, showing an alternative layout with up to 50 locations, including one spare location.

The project is roughly bounded by U.S. 20, which passes approximately two kilometers north of the project area, Ohio Route 4 on the east, and Ohio Routes 18 and 162 on the South.

Terrain in the area is flat overall with small undulations. Southern parts of the project area generally have more elevation change. The Sandusky river passes just to the west of the project area. Land use is primarily agricultural. Most land is cultivated, with some scattered stands of trees.

A final wind turbine type has not been selected for the project. Currently considered turbine models for this particular array are the Vestas V150 4.2 MW with a hub height of 105 meters; Siemens/Gamesa SG4.5-145 with a 107.5-meter hub height; and Nordex N149 4.5 MW with a 109-meter hub height. The turbine models considered for the previously-modeled turbine array were the GE 3.6-137, Acciona AW132, and Vestas V136 3.6 MW. The project will also include a single 67-90-112 MVA transformer at the collector substation and individual pad-mounted transformers at the base of each turbine.

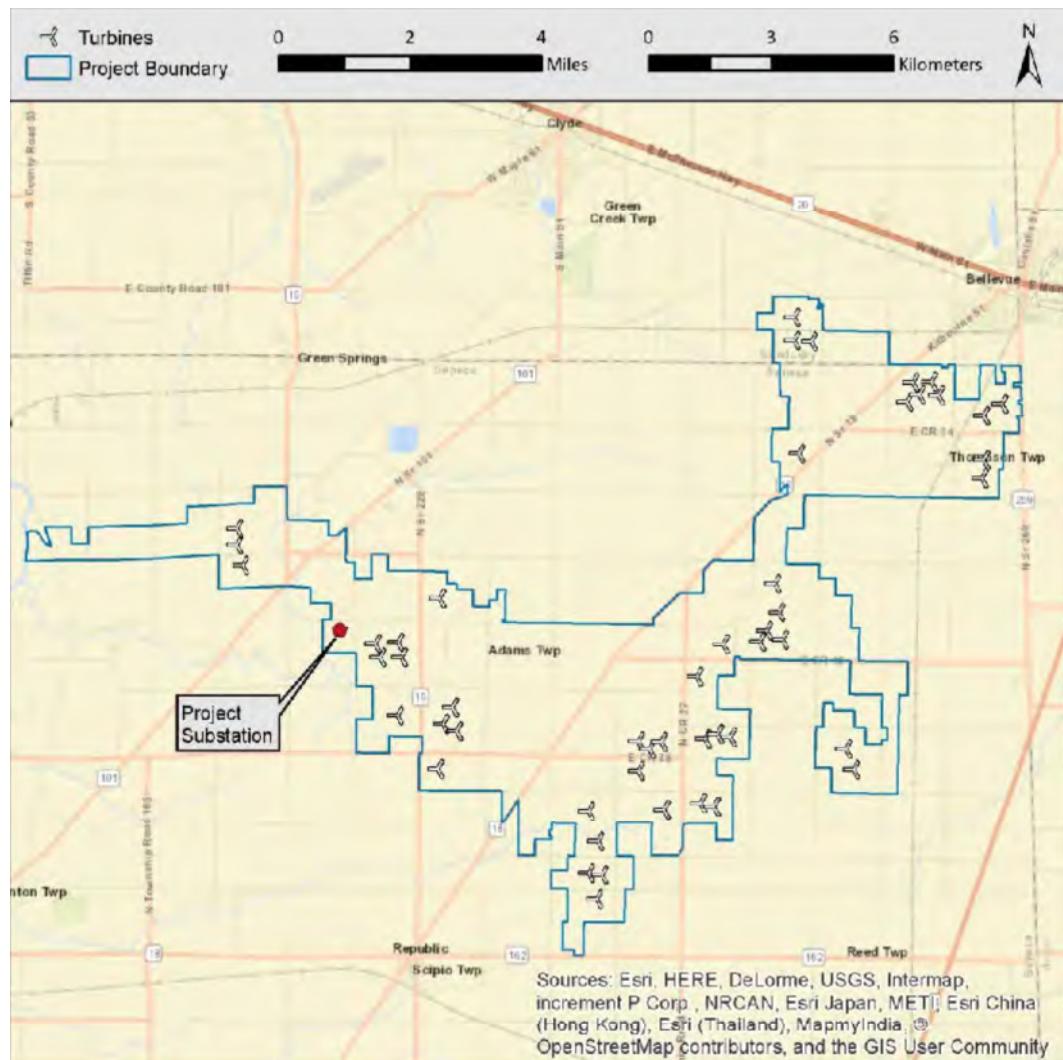

FIGURE 1: PROJECT AREA MAP

## 3.0 SOUND LEVEL LIMITS/GUIDELINES

---

### 3.1 | STATE STANDARDS

Sound levels from wind power projects are regulated under Section 4906-4-09(F) of the Ohio Administrative Code (“OAC”) which states:

(2) The facility shall be operated so that the facility noise contribution does not result in noise levels at any non-participating sensitive receptor within one mile of the project boundary that exceed the project area ambient nighttime average sound level (Leq) by five A-weighted decibels (dBA). During daytime operation only (seven a.m. to ten p.m.), the facility may operate at the greater of: the project area ambient nighttime Leq plus five dBA; or the validly measured ambient Leq plus five dBA at the location of the sensitive receptor. After measured ambient Leq plus five dBA at the location of the sensitive receptor. After commencement of commercial operation, the applicant shall conduct further review of the impact and possible mitigation of all project-related noise complaints through its complaint resolution process. Non-participating, as used in this context, refers to a property for which the owner has not signed a waiver or otherwise agreed to be subject to a higher noise level.

Based on ambient sound monitoring conducted at seven locations throughout the Republic project area (see Section 4), the existing nighttime background L<sub>eq</sub> in the area is 41 dBA. Applying the OPSB sound level limit results in a nighttime sound level limit of 46 dBA. As discussed in Section 4, the daytime sound levels are generally higher than the nighttime sound levels throughout the project area, so a higher daytime limit may be possible at some sensitive receptors, but for the purposes of this assessment, the nighttime sound level limit of 46 dBA is applied.

Section 4906-4-09(F) also limits the hours of construction activities that increase sound above ambient levels at sensitive receptors to the hours of 7 AM to 7 PM or dusk, whichever is later. Pile driving, blasting, and rock hammering are further restricted to the hours of 10 AM to 5 PM. There are also requirements regarding notification of property owners and tenants related to construction activities.

## **4.0 PRE-CONSTRUCTION BACKGROUND SOUND LEVELS**

---

Background sound monitoring was conducted to assess representative ambient sound levels in the project area to form the basis for the noise limit. This section of the report describes the monitoring performed and discusses the results obtained. It includes a description of the monitoring procedures, monitoring locations, sound data processing, and the results obtained for each of the monitoring locations. Observations and conclusions regarding the existing soundscapes at each monitoring location are included.

### **4.1 | DESCRIPTIONS OF THE MONITORING LOCATIONS**

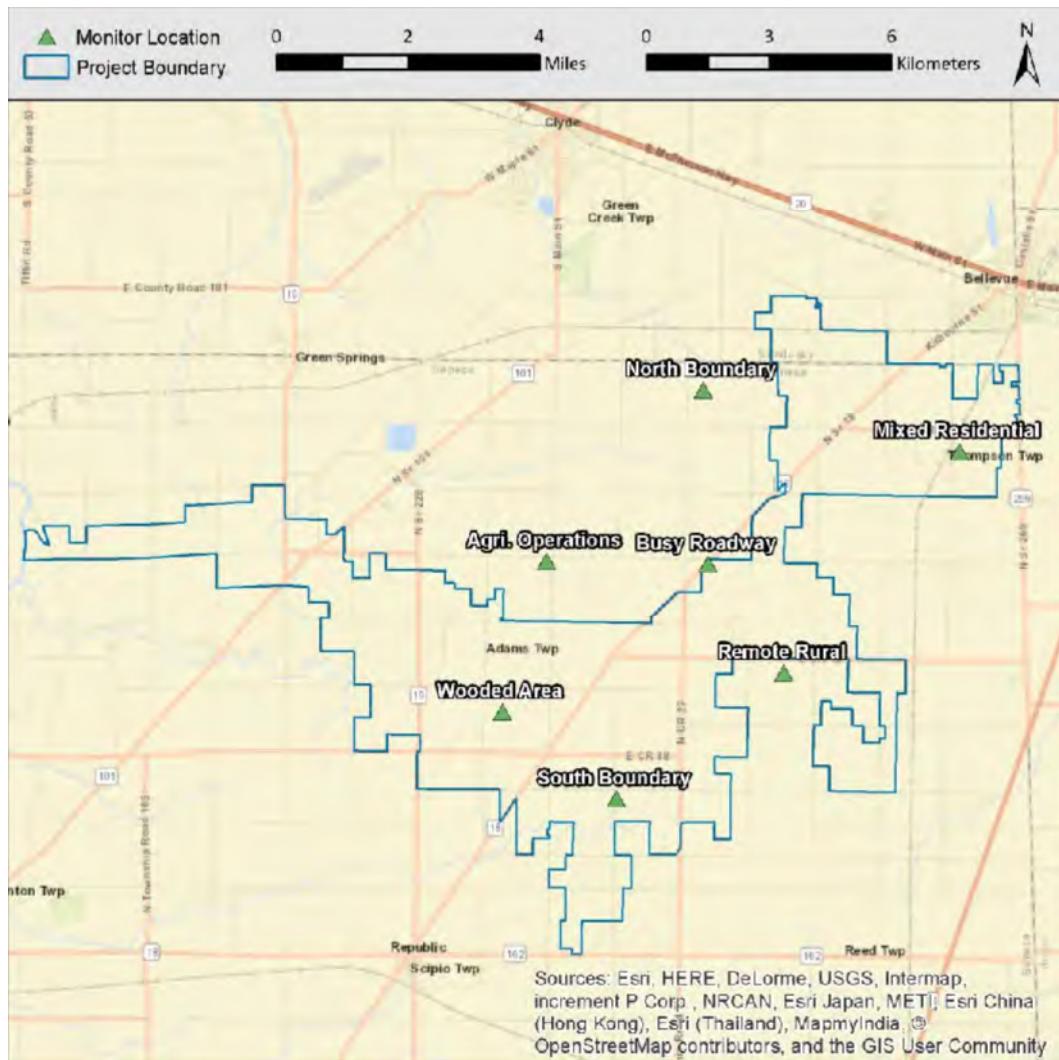

Background sound level monitoring was performed from February 3 through February 18, 2016 at seven different locations spread across the proposed project area. Each location was selected as representative of a given landscape or soundscape that would be in proximity of one or more of the proposed wind turbines. In placing monitors, consideration is also given to accessibility in winter weather and to the security of the monitoring equipment.

The seven sites are shown in Figure 2, and the reasons for selecting each are described below:

1. “North Boundary”: This location is near the northern extremity of the proposed project, on the boundary between Seneca and Sandusky Counties. This area represents a lower vehicle traffic agricultural area in the northern part of the project;
2. “Mixed Residential”: Flat Rock is one of the few higher-density residential areas within the proposed project boundary. It is also along a rail line with a crossing;
3. “Agricultural Operations”: Most of the area within the proposed project boundary is taken up with larger-scale agricultural operations and related low-density housing. Note that our monitoring took place in the winter and farming activities were not evident;
4. “Busy Roadway”: Most of the area is crossed with town roads (TR) and county roads (CR) with very light traffic. But the project area is also crossed by a few larger roadways. This site is near State Route 18 (SR18), which bisects the entire project area and where the traffic is significantly higher;
5. “Wooded Area”: The majority of the proposed project area is characterized by open agricultural fields. There are a few forested areas, where the soundscape includes a different mix of biogenic sources. This particular wooded area was selected because it was further from roadways but still accessible in wintertime;
6. “Remote Rural”: As stated above, most the area is open agricultural fields crossed by lightly-traveled roadways. This site represents an effort to find a quiet area that is still subject to agricultural activity; and,

7. “Southern Boundary”: This location is near the southern extremity of the proposed project. This location represents a lower traffic agricultural area in the southern part of the project.

Each monitoring location is described in detail below. Note that some of the installation photos were taken on February 2 or 3 when there had been no recent snowfall, while others were taken on February 11, when a light snow was on the ground.

**FIGURE 2: LONG-TERM MONITORING LOCATIONS FOR REPUBLIC WIND (PRE-CONSTRUCTION)**

## **NORTH BOUNDARY**

The monitor labeled “North Boundary” was located 375 meters (1,230 feet) east of Route TR79. The project boundary is located approximately 1,220 meters (4,000 feet) to the east, along TR80 and the border between Seneca and Sandusky Counties (County Route 62) is located approximately 700 meters (2,300 feet) to the north. The site is shown in Figure 3. A

two-building chicken operation was located about 454 meters (1,490 feet) to the north of the monitor.

The monitoring system and an anemometer were secured along the tree-line separating two parcels, as shown in Figure 4.

### **MIXED RESIDENTIAL**

The monitor labeled “Mixed Residential” was in the village of Flat Rock. It was placed 208 meters (682 feet) east of North County Road 29, 106 meters (348 feet) northeast of the Flat Rock Care Center. The site is shown in Figure 5. To the west of the monitor was the residential area; to the east were agricultural fields. The monitor was 392 meters (1,286 feet) from the closest point of approach of the rail line, and 515 meters (1,690 feet) from the crossing of that rail line with CR29.

The monitoring system, an anemometer, and a thermometer were secured along the tree-line separating the residential parcels from the farm fields, as shown in Figure 6.

### **AGRICULTURAL OPERATIONS**

The monitor labeled “Agricultural Operations” was located near the residence of an agricultural parcel at the corner of County Roads 32 and 21 in Clyde, Ohio as shown in Figure 7. The monitor was placed approximately 90 meters (300 feet) south of Country Road 32, and 120 meters (390 feet) west of Country Road 21. The participating parcel includes the residence, grain storage containers, and two equipment barns, all surrounded by agricultural fields.

The monitoring system and an anemometer were secured on the northern edge of the residential portion of the property, as shown in Figure 8.

### **BUSY ROADWAY**

The monitor labeled “Busy Roadway” was located 85 meters (279 feet) southeast of State Route 18 (SR18) and 149 meters (489 feet) south of County Road 32 (CR32), as shown in Figure 9. The monitor was placed along a small grove of trees in an open, untilled patch bordered by three agricultural fields. A residence was located 210 meters (689 feet) to the northeast, across CR32.

The monitoring system was secured near one of the trees in the grove, as shown in Figure 10.

### **WOODED AREA**

The monitor labeled “Wooded Area” was located 613 meters (2,011 feet) south of Town Road 138 (TR138) and 588 meters (1,929 feet) east of Town Road 179 (TR 179), as shown in Figure 11. The location was near a maple sugaring shack that was in operation for brief periods during monitoring. A large confinement facility was located across TR138, approximately 777 meters (2,550 feet) to the north of the monitor.

The monitoring system was secured within the trees on the northern edge of the woods, as shown in Figure 12.

### REMOTE RURAL AREA

The monitor labeled “Remote Rural Area” was located 355 meters (1,165 feet) south of County Road 46 (CR46) and 874 meters (2,867 feet) east of Town Road 80 (TR80), as shown in Figure 13. It was on the edge of a small grove of trees in the center of the adjacent agricultural fields. This location was also 351 meters (1,152 feet) to the west of the boundary line of the proposed project area near CR46. While the location and density of residences is similar in this area to others selected for monitoring, it is further from more heavily-traveled roads. It was 3.22 kilometers (2 miles) due west of the rail line that passes through Flat Rock.

The monitoring system was secured along the edge of the field and tree-line, as shown in Figure 14. The microphone is highlighted in the photograph.

### SOUTH BOUNDARY

The monitor labeled “South Boundary” was located 251 meters (823 feet) south of County Road 24 (CR24) and 96 meters (315 feet) east of Town Road 183 (TR183), as shown in Figure 15. This area is near the southern boundary of the proposed project area: the boundary follows CR24 and then jogs south to Town Road 124 (TR124) for just over one mile.

The monitoring system and an anemometer were secured along south edge of a stand of trees in this area, as shown in Figure 16.

## 4.2 | MONITORING METHODOLOGY

### DATA ACQUISITION

Sound levels at each monitoring location were measured using one of three sound level meters: the Cesva SC-310, Svantek SV979, or Rion NL-22. All sound level meters logged A-weighted equivalent continuous sound levels once each second. The Cesva and Svantek models are ANSI/IEC Type 1 sound level meters, and logged 1/3-octave-band spectral sound levels once each second. The Rion model used at the “Busy Roadway” location is an ANSI/IEC Type 2 sound level meter. It did not log spectral sound levels.

Each sound level meter’s microphone was mounted on a wooden stake at a height of approximately 1.2 meters (4 feet) and covered with a weather-resistant windscreen. The windscreen acts to reduce the influence of wind-induced self-noise on the measurements.

Real time audio was recorded continuously at each location using the signal acquired through the sound level meter microphone. The Svantek SV979 meters recorded WAV audio internally. The analog signals from each of the other meters were input to external digital audio recorders.

Average wind speeds and maximum gust speeds were logged once per minute at four locations throughout the site using ONSET Hoboware anemometers. Air temperature was logged once per minute at the “Mixed Residential” location.

### DATA ANALYSIS

After the monitoring period, 1-second logged sound level data were compiled in 10-minute periods. Data from those periods during which weather conditions exceeded the operational ranges of the instrumentation were removed from results. These conditions include maximum gust speeds above 5 m/s (11 mph), temperatures below -10 °C (14 °F), or precipitation in the form of rain. (Snow periods are not excluded.) Other data periods were removed for seasonal sound sources (snow plows, snowmobiles, etc.), anomalous activities in the immediate vicinity of the microphones (such as interaction of people or animals with the equipment), and during station calibration/check-up.

For each monitor site, results are presented as graphs of sound levels and maximum wind (gust) speed as a function of time throughout the monitoring period. Two sound level metrics are plotted in each graph: equivalent continuous sound levels ( $L_{eq}$ ) and 10<sup>th</sup>-percentile sound levels ( $L_{90}$ ). The data which were excluded from summary processing are included in the graphs but shown in lighter colors.

## 4.3 | MONITORING RESULTS

### SUMMARY OF METEROLOGICAL DATA

Strong winds were common throughout the monitoring period, and temperatures dropped below -10 °C (14 °F) several times. Temperatures during the monitoring period ranged from a low of -19.1° C (-2.4° F) to a high of 15.6° C (60.1° F). The maximum wind speeds and

gusts recorded at the four sites equipped with anemometry are listed in Table 1. Over the 15 days of monitoring, precipitation fell as rain on February 8 and February 15.<sup>1</sup> The exact rain periods at each site were verified from their respective audio recordings.

**TABLE 1: MAXIMUM MEASURED WIND SPEEDS BY SITE**

Monitoring Location	Max Wind Speed		Max Gust Speed		Average Wind Speed	
	m/s	mph	m/s	mph	m/s	mph
Agricultural Operations	9.1	20.3	12.1	27.0	1.7	3.8
Mixed Residential	7.1	15.8	11.3	25.3	1.4	3.2
North Boundary	6.8	15.2	10.8	24.2	1.3	2.9
Southern Boundary	10.3	23.1	13.6	30.4	1.6	3.5

## SUMMARY OF SOUND LEVELS

The equivalent continuous sound level ( $L_{eq}$ ) and tenth-percentile sound level ( $L_{90}$ ) data logged at each monitoring location are plotted as time history graphs, along with the maximum 10-minute gust speed and temperature in Figures 17 through 37. (For an explanation of the sound level metrics and their use, see Appendix A, “A Primer on Sound and Noise”.) Each time history graph spans one calendar week for ease of viewing. Periods that have been excluded from the averaging of sound levels due to high wind, low temperature, rain, or anomalous events, are indicated on each graph. However, the original data for those periods are still shown, using lighter colors. Results specific to each monitor location are described in the following sections.

All the monitors were within audible range of freight train passby events (and their horns at crossings). Additionally, aircraft overflights, mostly by commercial jets operating at cruise altitudes, were evident at every site. All the monitors were near dormant farm fields. As the monitoring occurred in the winter, field farming activities were not evident in the data.

Summary sound levels for the monitoring period at all sites are presented in Table 2. They include the equivalent continuous average ( $L_{eq}$ ), and the 10<sup>th</sup>-percentile ( $L_{90}$ ), 50<sup>th</sup>-percentile ( $L_{50}$ ) and 90<sup>th</sup>-percentile ( $L_{10}$ ) statistical levels for the entire period, for the daytime periods, and for the nighttime periods.<sup>2</sup>

The Mixed Residential monitor was the closest monitor to a residential area (“in town”). It recorded the highest average levels as a result of frequent use of the nearby Flat Rock Care facility parking lot. The Busy Roadway monitor was exposed to regular high-speed car and truck passbys.

<sup>1</sup> Rain periods were identified from historical meteorology data available online Weather Underground stations KOHMONRO6 and KOHREPUB2, at <http://www.wunderground.com>.

<sup>2</sup> Daytime is defined here as the period from 7:00 AM to 10:00 PM; nighttime is defined here as the period from 10:00 PM to 7:00 AM the following day.

The quietest sites were the Southern Boundary and the Wooded Area, which were more distant from roads and areas of frequent human activity.

The relatively larger differences between equivalent continuous levels ( $L_{eq}$ ) and lower tenth-percentile levels ( $L_{90}$ ) at most of the sites indicate that the soundscapes are dominated by transient events resulting from human activity. Weather patterns (mostly wind) also influenced sound levels. Thus, only some of the data show a typical anthropogenic diurnal pattern, where sound levels are higher during the day and lower at night.

The OPSB level limit is calculated from the arithmetic average of the site-wide nighttime equivalent average sound levels ( $L_{eq}$ ) plus 5 dB. The site-wide average sound levels are shown in the last row of Table 2. Among all seven sites in the Republic project area, the average nighttime  $L_{eq}$  is 41 dB, which results in an OPSB project-only sound level limit of 46 dBA  $L_{eq\ 1-hr}$ .

**TABLE 2: SUMMARY SOUND LEVELS FROM PRE-CONSTRUCTION MONITORING**

Location	Sound Level (dBA)											
	Overall				Day				Night			
	$L_{eq}$	$L_{90}$	$L_{50}$	$L_{10}$	$L_{eq}$	$L_{90}$	$L_{50}$	$L_{10}$	$L_{eq}$	$L_{90}$	$L_{50}$	$L_{10}$
Agricultural Operations	43	26	35	46	44	29	37	47	40	24	30	41
Busy Roadway	50	27	39	54	52	32	42	55	47	24	33	49

<b>Arithmetic Average</b>	44	25	34	44	45	28	35	45	<b>41</b>	23	30	41

## RESULTS AT EACH MONITORING LOCATION

### North Boundary

The overall  $L_{eq}$  at the North Boundary monitoring location was 47 dBA. The daytime and nighttime  $L_{eq}$  were 48 and 44 dBA, respectively. These levels were higher than the  $L_{10}$  for the same period, which indicates that the maximum sound levels over the period were brief, but relatively high. This is due to the preponderance of train horn blasts at the crossings of the east-west rail line about 1 mile (1.52 km) north of the site. The overall  $L_{90}$ , as an indication of the residual sound level, was lower: 27 dBA overall, 28 dBA daytime, and 25 dBA nighttime.

No sound anomalies were identified and excluded from the data analysis at this location. None of the transient sounds were out of character for the area, and they did not take place abnormally close to the microphone.

The sound level meter was taken out of service for one hour after midnight on February 11, 2016 to download data and replace the system's batteries.

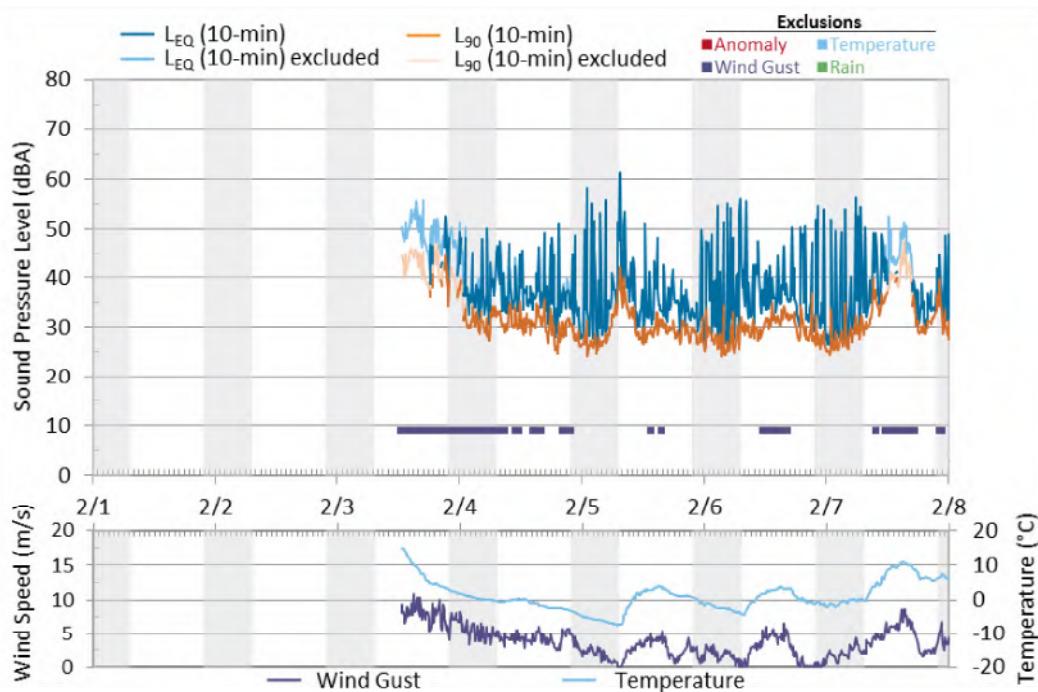

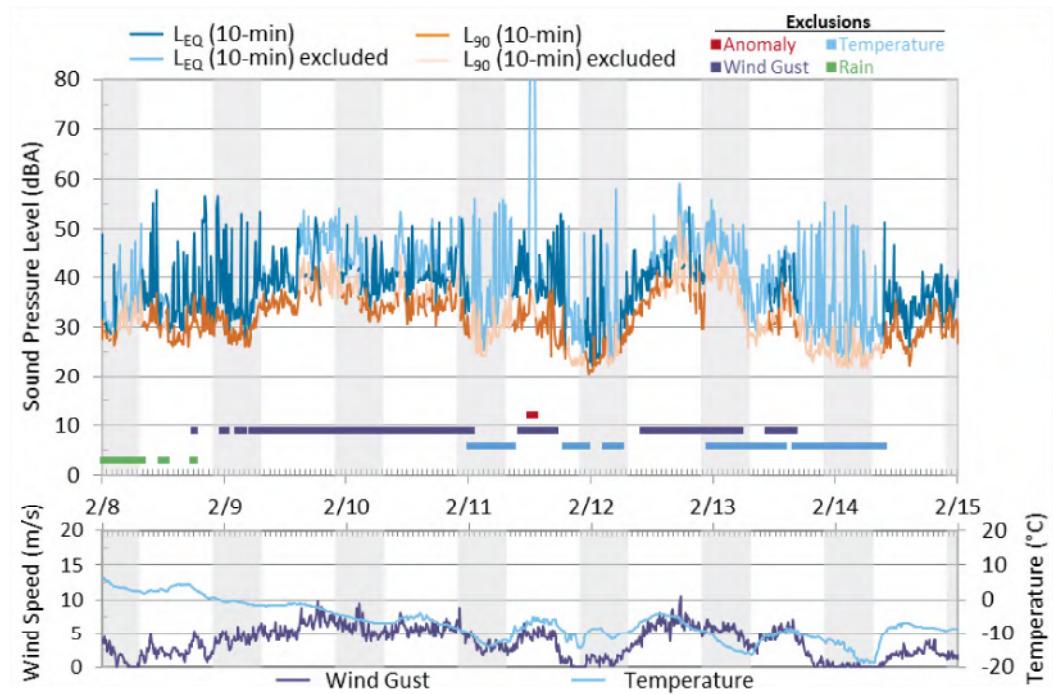

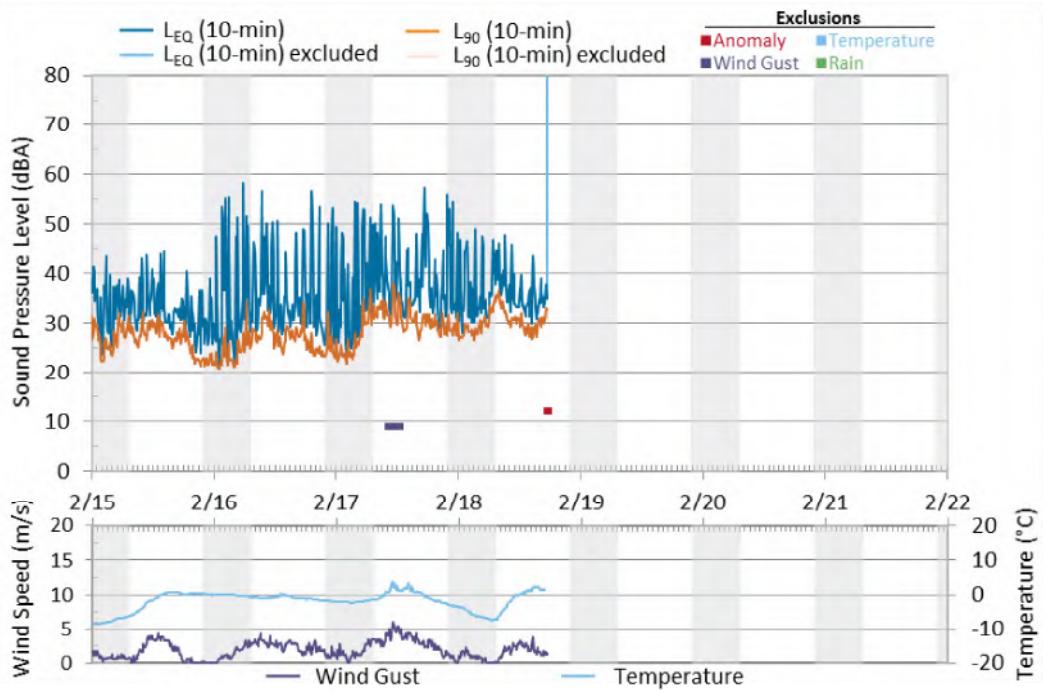

FIGURE 17: MONITOR DATA, NORTH BOUNDARY SITE, FEBRUARY 3-7, 2016

**FIGURE 18: MONITOR DATA, NORTH BOUNDARY SITE, FEBRUARY 8-14, 2016**

**FIGURE 19: MONITOR DATA, NORTH BOUNDARY SITE, FEBRUARY 15-18, 2016**

### Mixed Residential

The overall  $L_{eq}$  at the Mixed Residential monitoring location was 51 dBA, the highest of the seven sites. The daytime and nighttime  $L_{eq}$  were the same, at 51 dBA. This indicates a relatively high amount of regular, but transient anthropogenic noise. It also indicates the proximity to the rail line, and the sounding of train horns both day and night. The overall  $L_{90}$ , was lower: 29 dBA overall, 31 dBA daytime, and 27 dBA nighttime.

Of the many transient events identified in the sound level data for this site, none were excluded as anomalies. This is because they were not out of character for the area, and they did not take place abnormally close to the microphone.

The sound level meter was taken out of service from 7:00 PM on February 10, 2016 until 11:30 AM on February 11, 2016 to download data and charge the system's batteries.

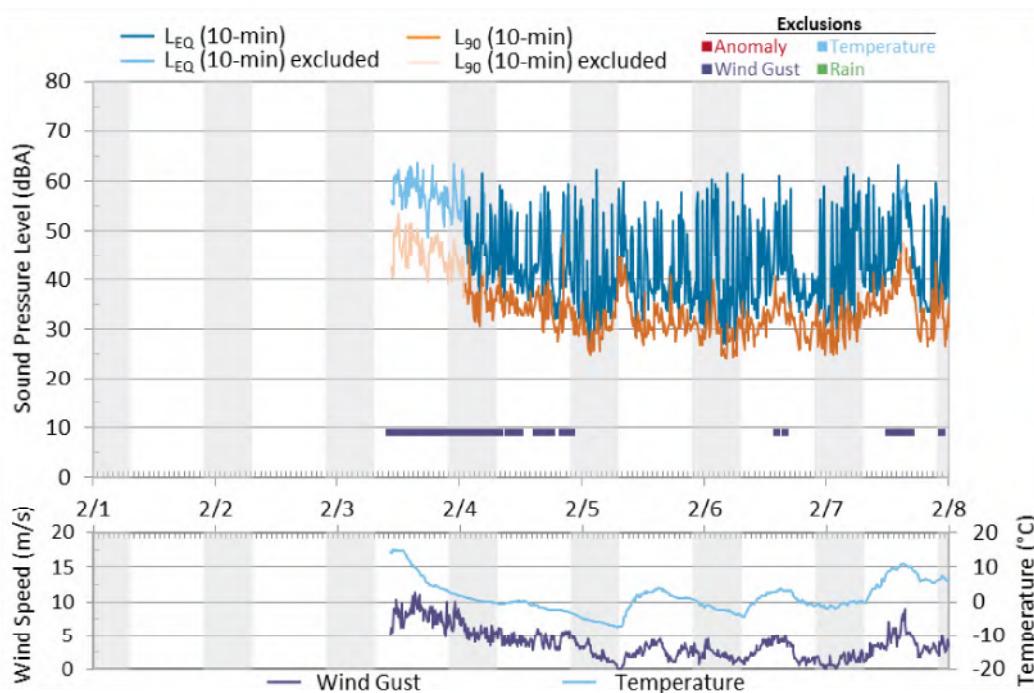

FIGURE 20: MONITOR DATA, MIXED RESIDENTIAL SITE, FEBRUARY 3-7, 2016

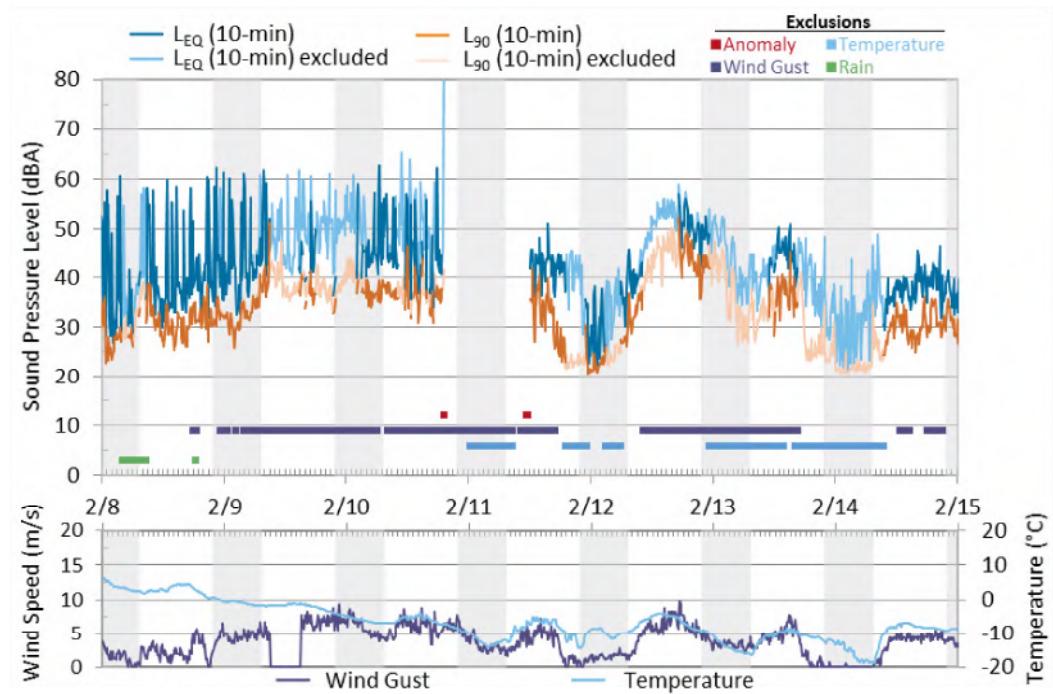

FIGURE 21: MONITOR DATA, MIXED RESIDENTIAL SITE, FEBRUARY 8-14, 2016

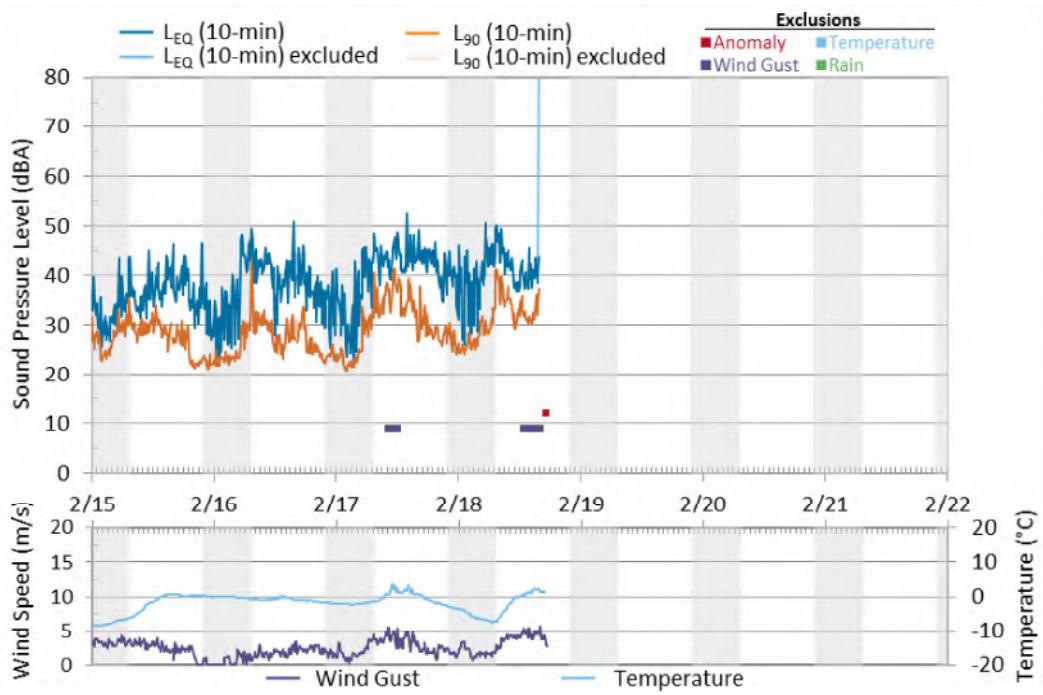

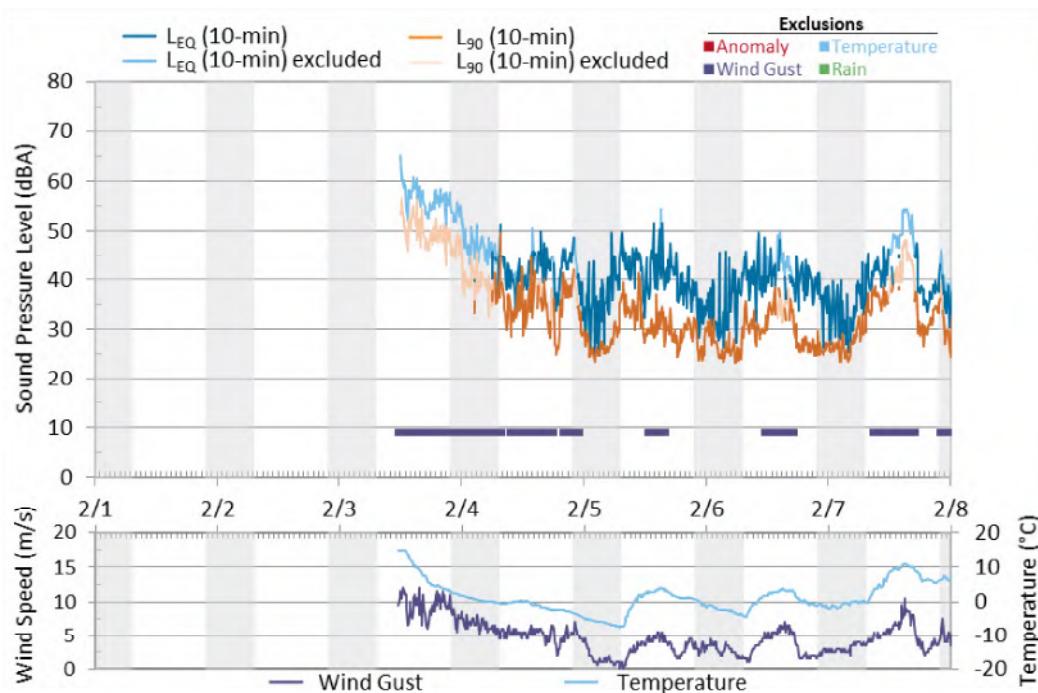

FIGURE 22: MONITOR DATA, MIXED RESIDENTIAL SITE, FEBRUARY 15-18, 2016

### Agricultural Operations

The overall  $L_{eq}$  at the Agricultural Operations monitoring location was 43 dBA. The daytime and nighttime  $L_{eq}$  were 44 and 40 dBA, respectively. These levels were within 3 dB of the  $L_{10}$  for the same period. This is indicative of transient anthropogenic events. The overall  $L_{90}$ , as an indication of the background sound level, was lower: 26 dBA overall, 29 dBA daytime, and 24 dBA nighttime.

Anomalies at this site that were excluded from data analysis included children playing very near the microphone on February 15 and February 16, 2016, along with car horn and automobile door slams during the same periods.

The sound level meter was taken out of service from 6:00 PM on February 10 until 10:00 AM on February 11 to download data and charge the system's batteries.

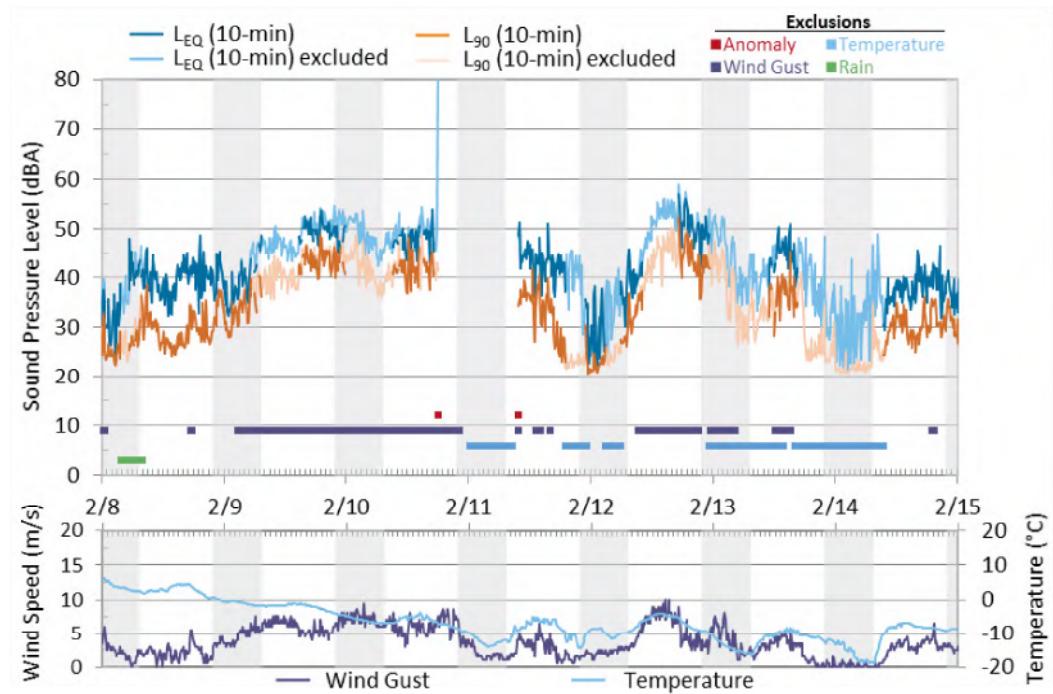

FIGURE 24: MONITOR DATA, AGRICULTURAL OPERATIONS SITE, FEBRUARY 8-14, 2016

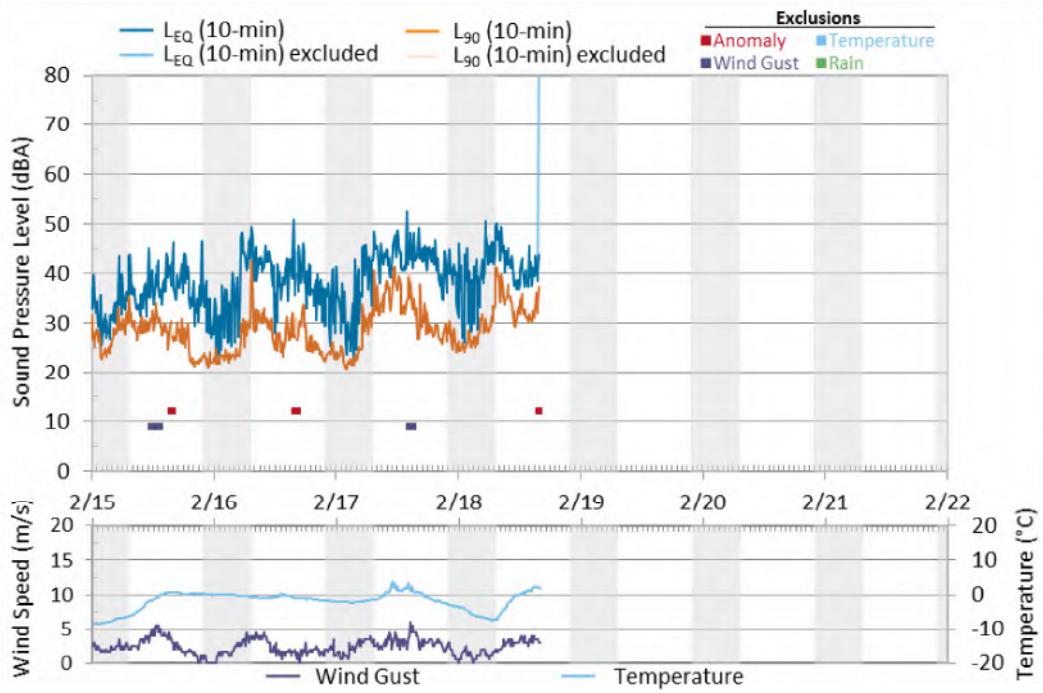

FIGURE 25: MONITOR DATA, AGRICULTURAL OPERATIONS SITE, FEBRUARY 15-18, 2016

### Busy Roadway

The overall  $L_{eq}$  at the Busy Roadway monitoring location was 50 dBA. The daytime and nighttime  $L_{eq}$  were 52 and 47 dBA, respectively. The overall  $L_{90}$  was 27 dBA overall, 32 dBA daytime, and 24 dBA nighttime. These patterns are indicative of transient anthropogenic noise. The 8 dB difference between daytime and nighttime  $L_{90}$  indicate a diurnal pattern, mostly caused by reduced roadway traffic at night. Confirmation of this can be found by the convergence of the  $L_{eq}$  and  $L_{90}$  at night, indicating a reduction in transient sounds such as car passbys.

No sound anomalies were identified and excluded from the data analysis at this location. None of the transient sounds out of character for the area, and they did not take place abnormally close to the microphone. A long period of data, from 7:50 PM on February 8 until 2:00 PM on February 10, 2016, was excluded due to wind noise. The exact wind speed was not available, because the anemometer arm froze, but the sound levels (and lack of diurnal pattern) were indicative of very high winds. After comparing to the conditions at the other sites, that entire time period was excluded.

The sound level meter was not taken out of service, but the audio recorder was disconnected from 7:00 PM on February 10 until 11:30 AM on February 11, 2016 to download data.

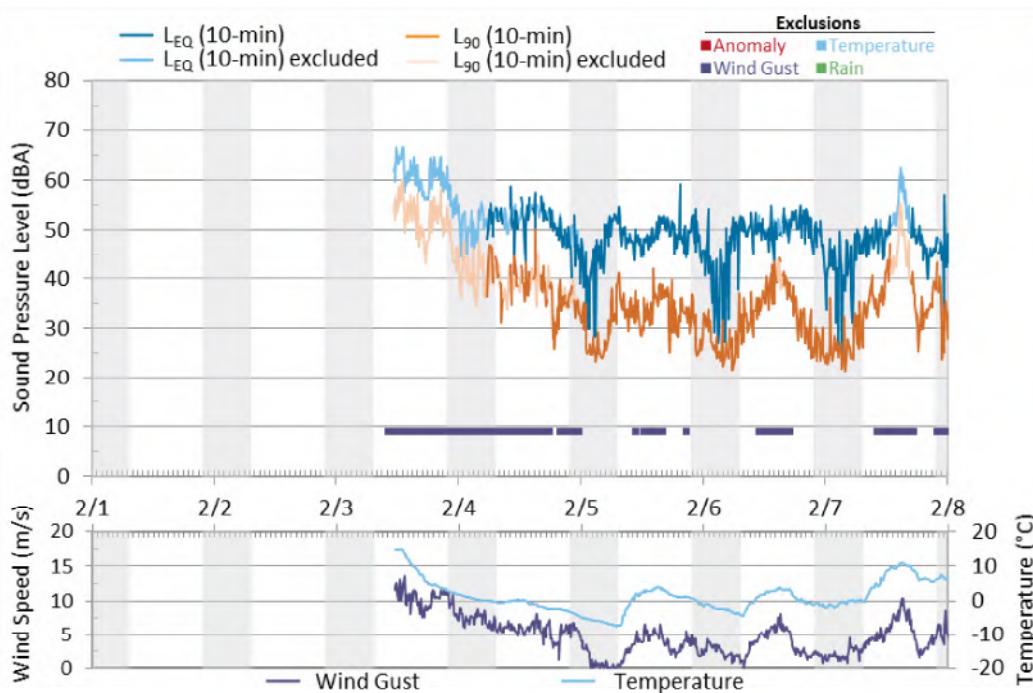

FIGURE 26: MONITOR DATA, BUSY ROADWAY SITE, FEBRUARY 3-7, 2016

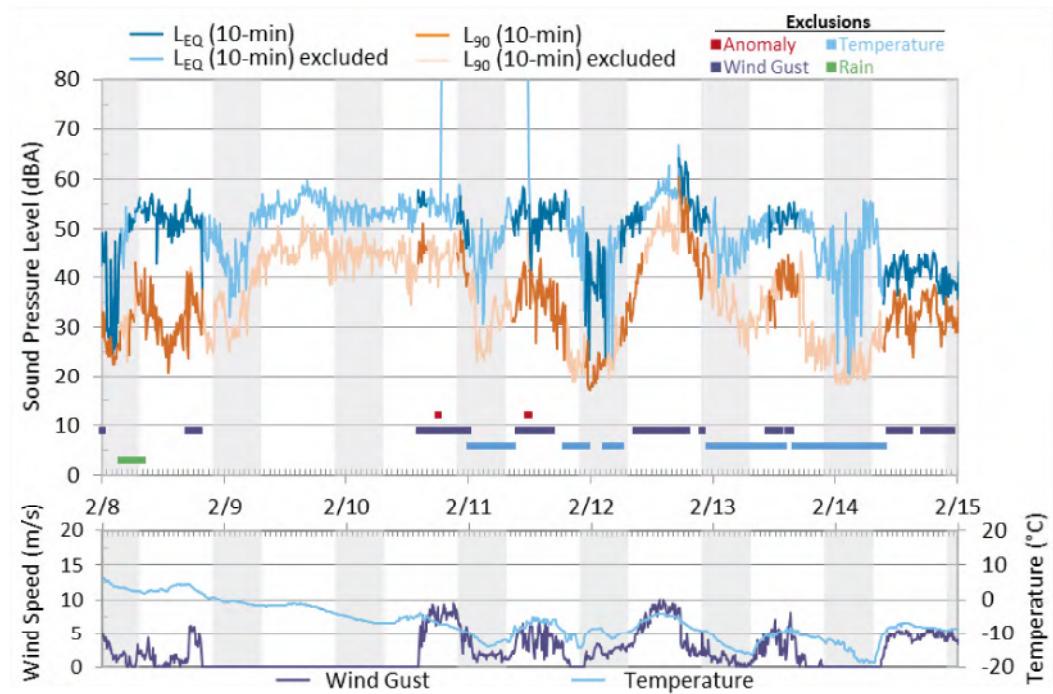

FIGURE 27: MONITOR DATA, BUSY ROADWAY SITE, FEBRUARY 8-14, 2016

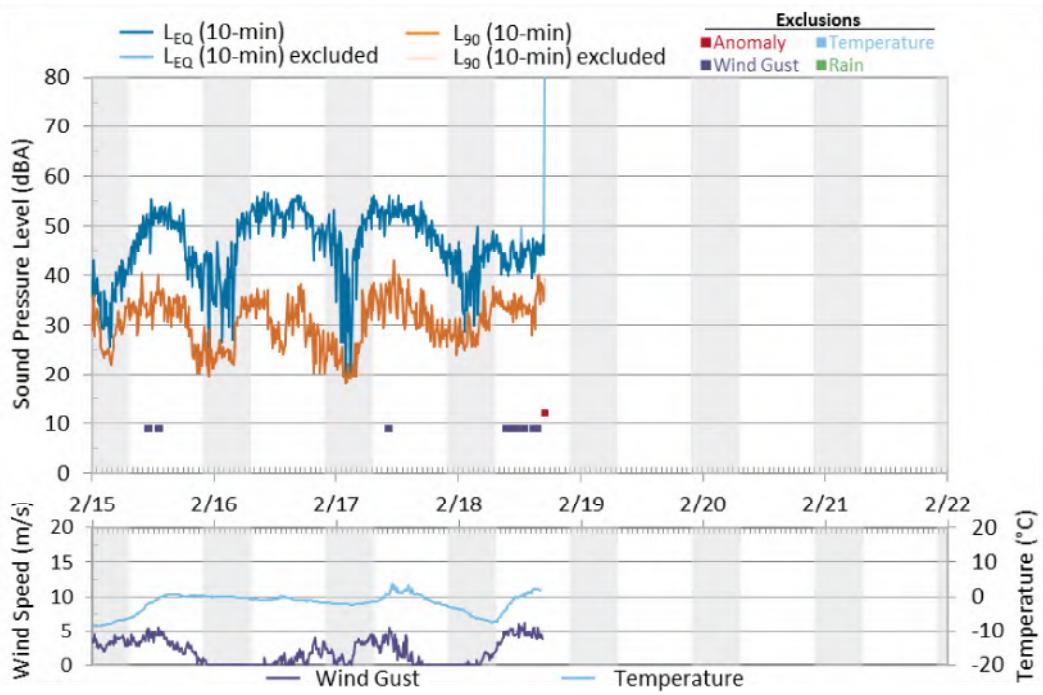

FIGURE 28: MONITOR DATA, BUSY ROADWAY SITE, FEBRUARY 15-18, 2016

### Wooded Area

The overall  $L_{\text{eq}}$  at the Wooded Area monitoring location was 36 dBA, the quietest of monitored locations. The daytime and nighttime  $L_{\text{eq}}$  were 37 and 34 dBA, respectively. These levels were within 3 dB of the  $L_{10}$  for the same period, indicating some amount of transient anthropogenic noise. The overall  $L_{90}$  was 23 dBA overall, 25 dBA daytime, and 21 dBA nighttime. The small difference (4 dB) between daytime and nighttime levels indicates that background sound in the area does not follow a strong diurnal pattern.

Anomalies excluded from data analysis at this site included:

- A very low military aircraft flight directly over the microphone on February 4;
- Tractor operations in the woods very near the microphone on February 6;
- A group of people partying in the woods on February 7;
- Gunshots near the microphone on February 7 and February 14; and
- An unmuffled ATV approaching the microphone on February 16 and February 18.

The sound level meter was taken out of service from 6:15 PM on February 10 until 10:00 AM on February 11, 2016 to download data and charge the system's batteries.

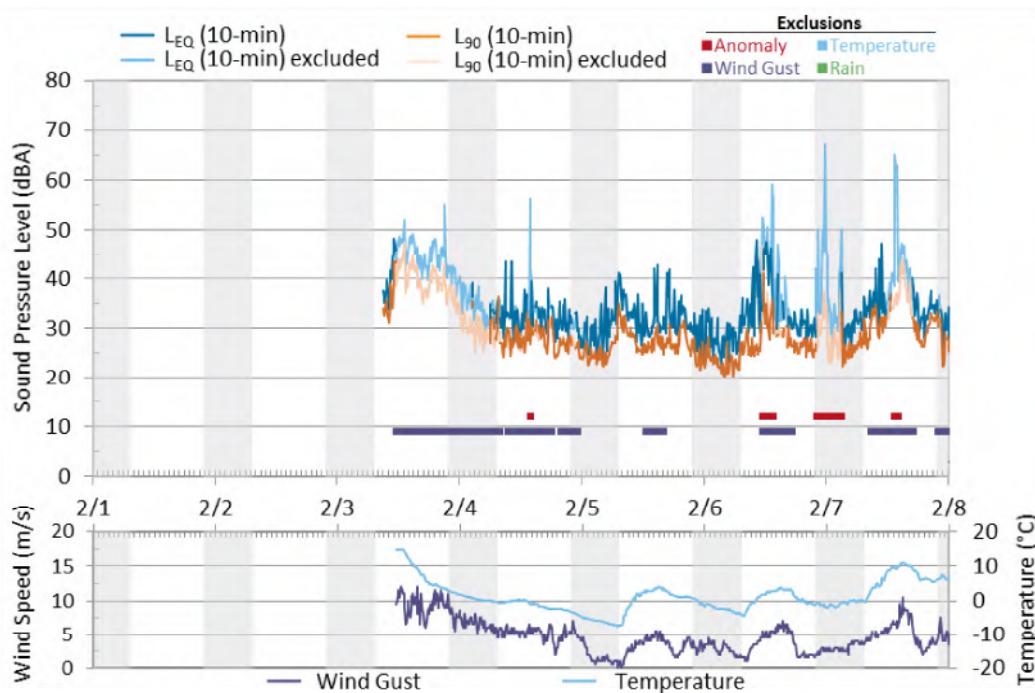

FIGURE 29: MONITOR DATA, WOODED AREA SITE, FEBRUARY 3-7, 2016

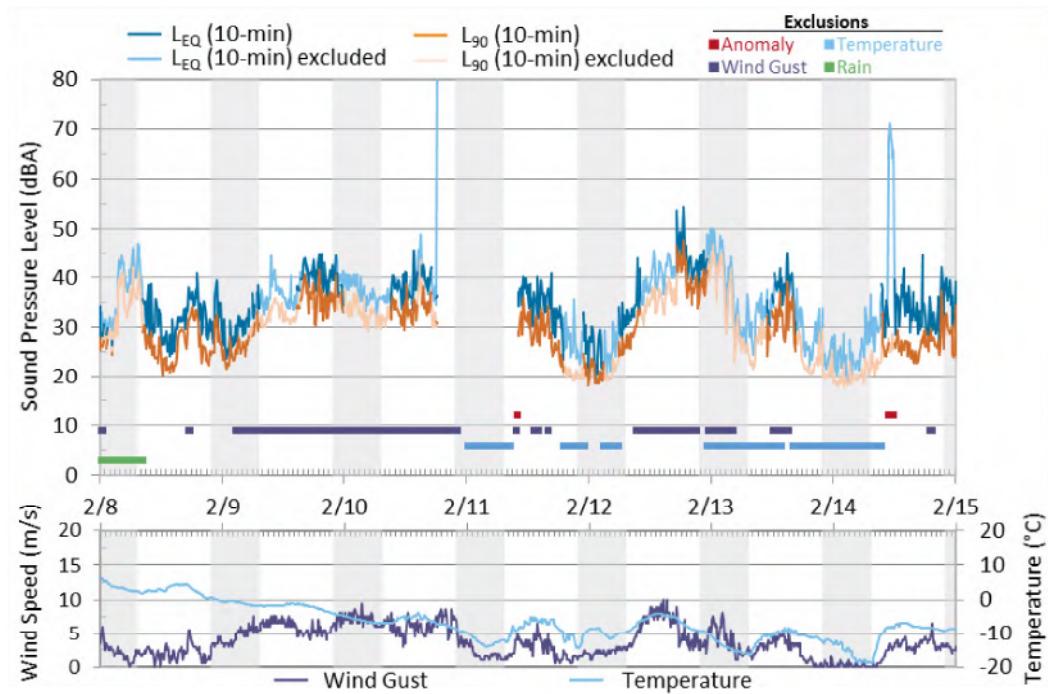

FIGURE 30: MONITOR DATA, WOODED AREA SITE, FEBRUARY 8-14, 2016

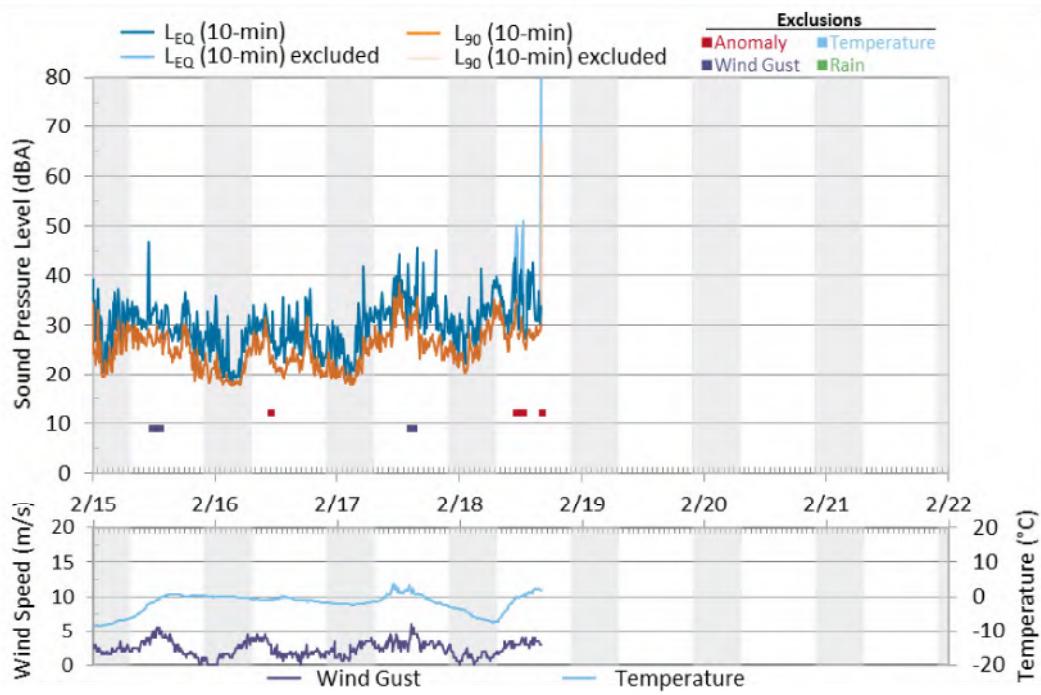

FIGURE 31: MONITOR DATA, WOODED AREA SITE, FEBRUARY 15-18, 2016

### Remote Rural

The overall  $L_{eq}$  at the Remote Rural Area monitoring location was 42 dB. The daytime and nighttime  $L_{eq}$  were 43 and 39 dBA, respectively. These levels were within 2 dB of the  $L_{10}$  for the same period, indicating transient anthropogenic noise. The overall  $L_{90}$  was 24 dBA overall, 26 dBA daytime, and 21 dBA nighttime. The sound levels tended to follow a diurnal pattern, but train horns at nearby crossings during the night raised the nighttime  $L_{eq}$ .

No sound anomalies were identified and excluded from the data analysis at this location. None of the transient sounds out of character for the area, and they did not take place abnormally close to the microphone.

The sound level meter was taken out of service from midnight on February 10 until 11:10 AM on February 11, 2016 to download data and charge the system's batteries.

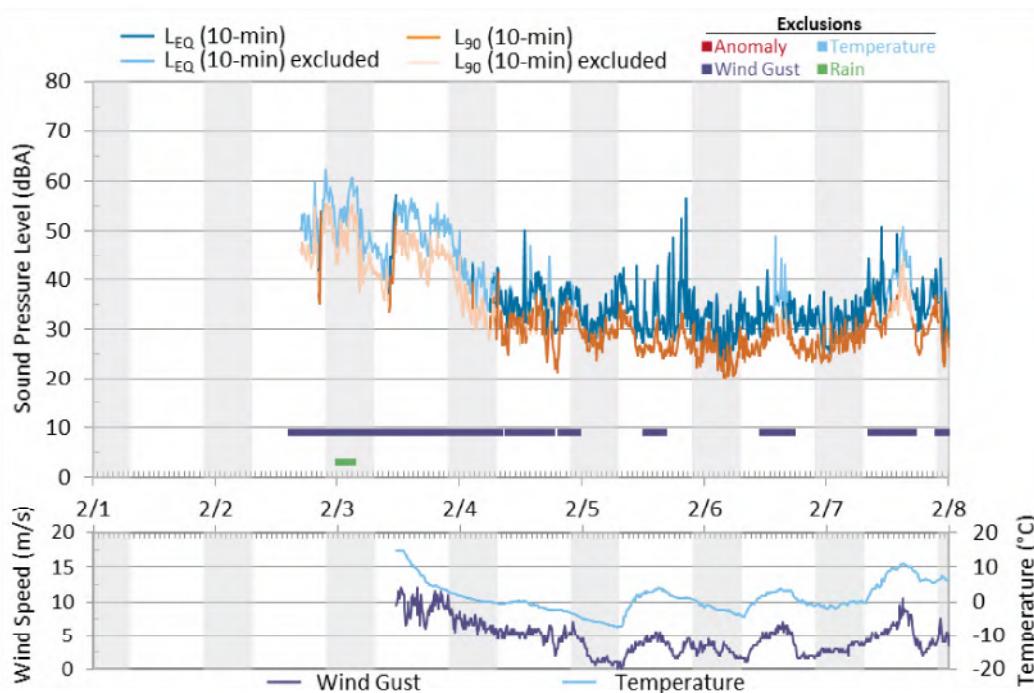

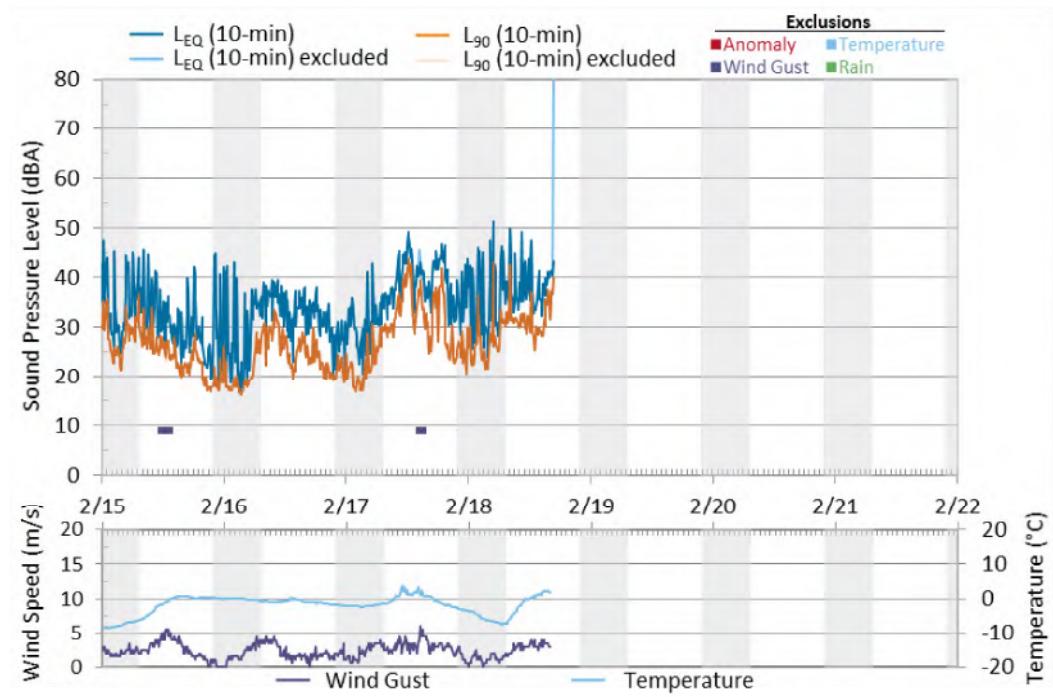

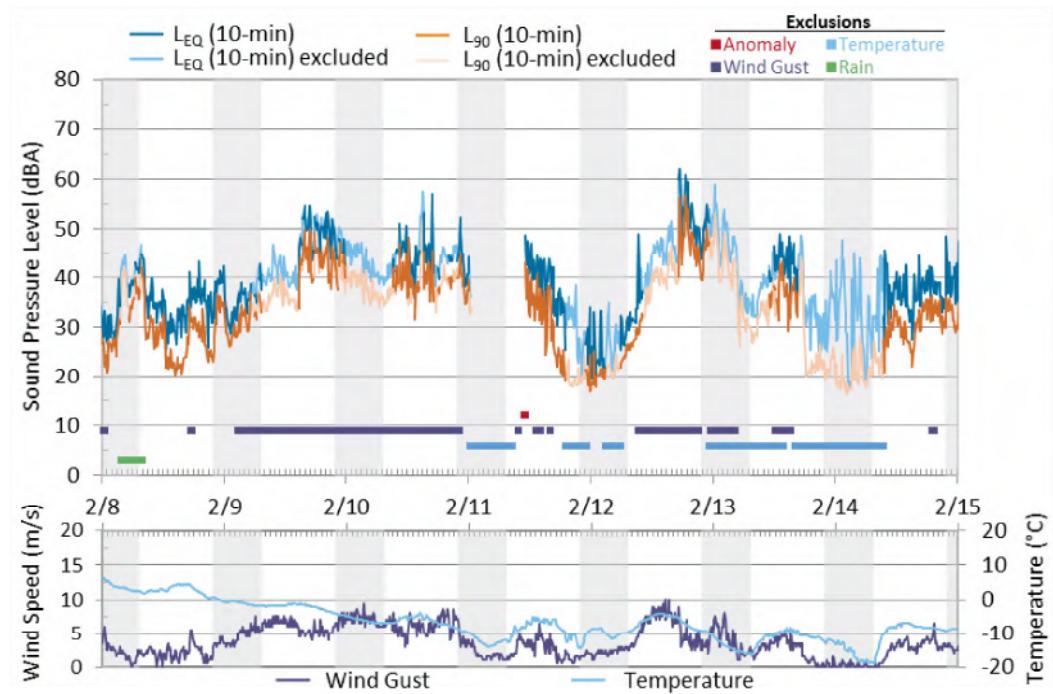

FIGURE 32: MONITOR DATA, REMOTE RURAL SITE, FEBRUARY 3-7, 2016

### Southern Boundary

The overall  $L_{eq}$  at the Southern Boundary monitoring location was 37 dBA, the second-quietest monitoring location. The daytime and nighttime  $L_{eq}$  were similar, at 38 and 34 dBA, respectively. These levels were within 3 dB of the  $L_{10}$  for the same period. This indicates a relatively high amount of transient anthropogenic noise. The overall  $L_{90}$  was lower: 21 dBA overall, 23 dBA daytime, and 17 dBA nighttime. These were the lowest of all the sites and tended to be more strongly diurnal. Train horns were not as prevalent.

A single anomaly was excluded from data analysis at this site: an unmuffled ATV approached the monitor on February 6, 2016.

The sound level meter was taken out of service from 6:30 PM on February 10 until 10:30 AM on February 11, 2016 to download data and charge the system's batteries.

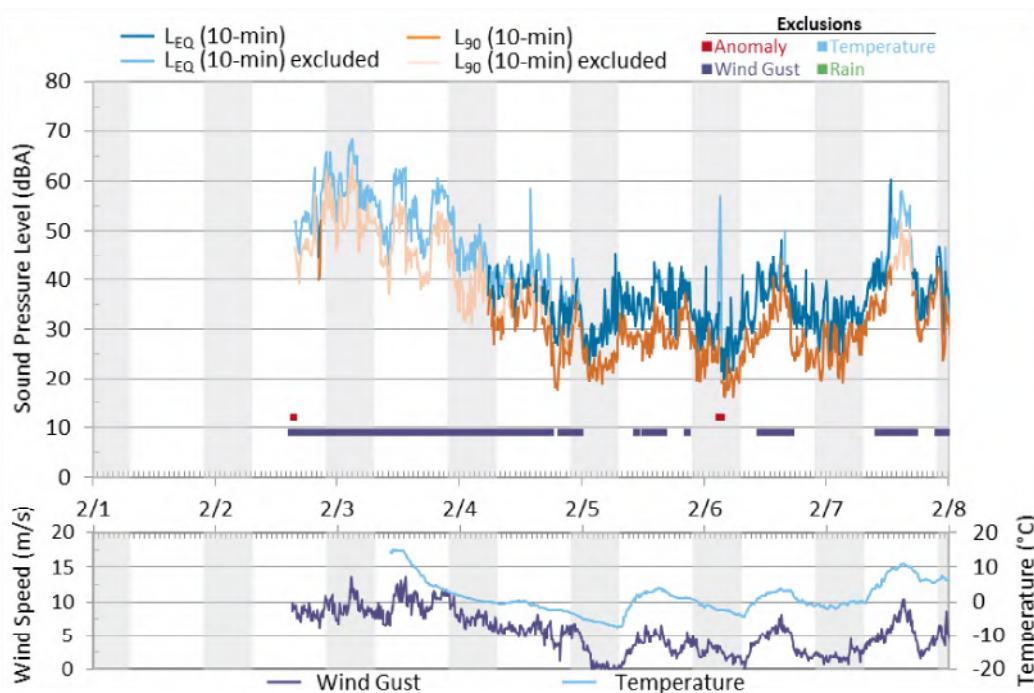

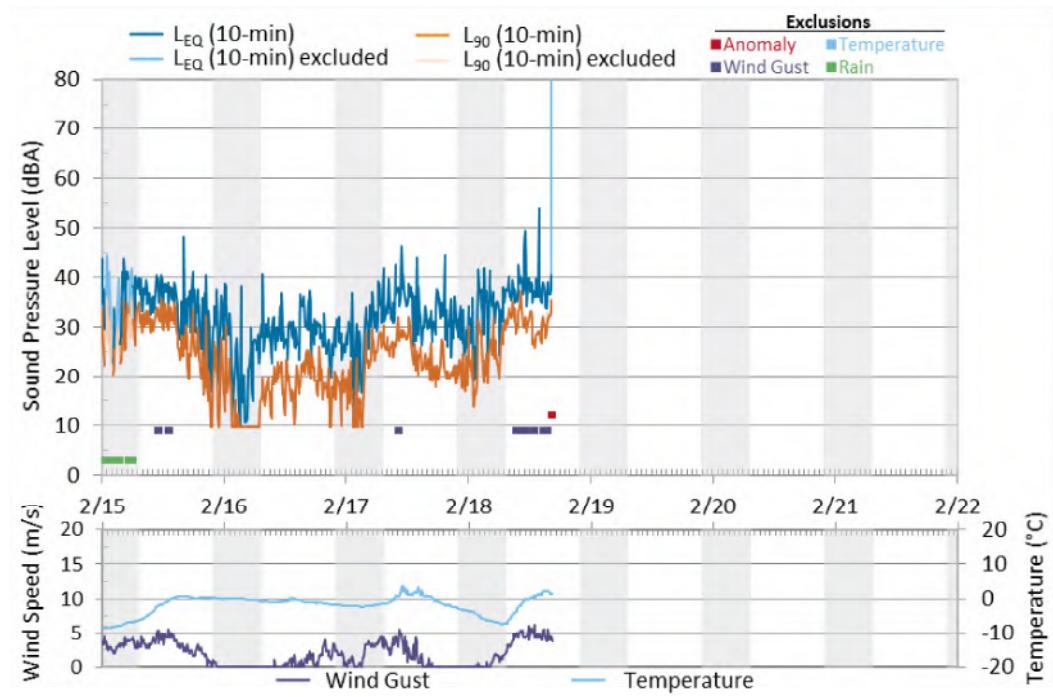

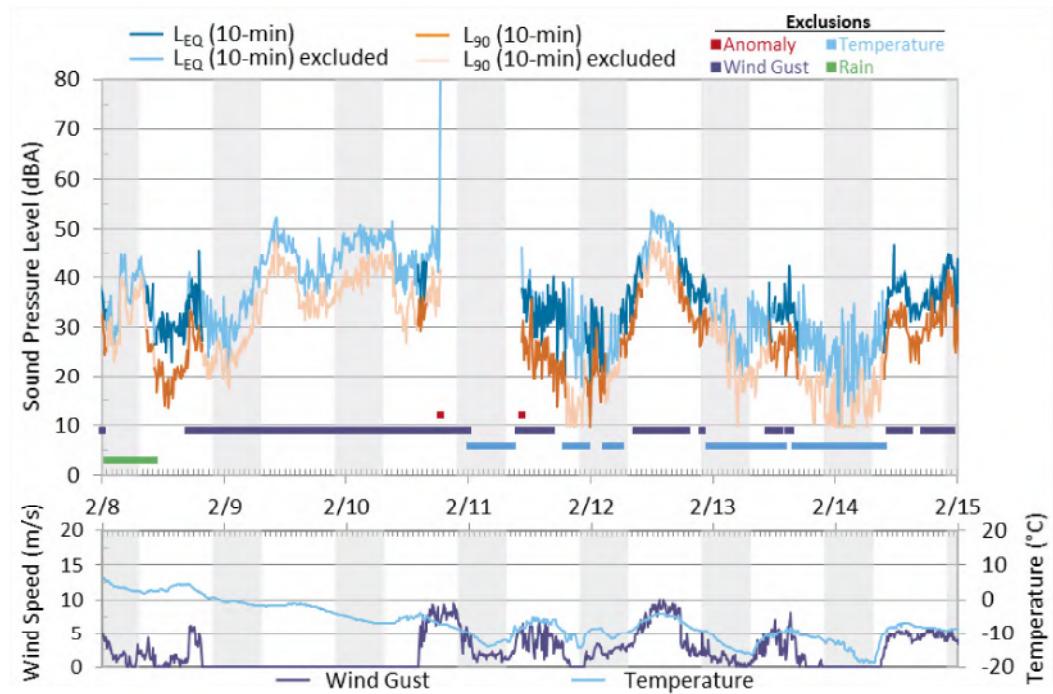

FIGURE 35: MONITOR DATA, SOUTH BOUNDARY SITE, FEBRUARY 3-7, 2016

## 5.0 ISSUES SPECIFIC TO WIND TURBINE SOUND

---

### 5.1 | SOUND EMISSIONS FROM WIND TURBINES

Wind turbines generate two principle types of noise: aerodynamic noise, produced from the flow of air around the blades, and mechanical noise, primarily from the gearbox and generator within the nacelle.

#### AERODYNAMIC NOISE

Aerodynamic (airflow) sound is the primary source of noise associated with wind turbines. These acoustic emissions can be either tonal (with an identifiable pitch) or broadband (spread over many frequencies).

Wind turbines emit aerodynamic broadband noise as air flows over and around the moving blades, and as those blades interact with atmospheric turbulence. These mechanisms result in a characteristic “whooshing” sound through several mechanisms (refer to Figure 38):

- **Flow separation:** When air flows quickly over any wing, it begins with a smooth “laminar” flow, but soon separates from the wing surface, becoming turbulent or “rough”. In most cases, including turbine blades, the amount of separation is related to the angle of the blade relative to the incoming air. The greater the angle, the more separation turbulence occurs: the more turbulence generated by the wing, the more sound is produced by the turbulence. In the limit, the wing can “stall”; there is so much turbulence that it is no longer providing lift. This is the noisiest condition for blade-induced turbulence. Wind turbines are programmed to avoid stall conditions.
- **Inflow turbulence:** As each blade passes around its full circle, it encounters many variations in the speed of the air flowing into the blade. In particular, the wind itself will naturally have eddies of different sizes, which is also a form of turbulence. Inflow turbulence noise occurs when the rotor blades encounter this atmospheric turbulence. The quick variations in air pressure on a rotor blade causes fluctuating aerodynamic loading on the blade. A small portion of the energy in these fluctuations can translate into sound. Sound from inflow turbulence varies across a wide range of frequencies, but for wind turbines it is most significant at frequencies below 500 Hz.
- **Trailing edge turbulence:** As the air passes the rear, or trailing edge, of the blade, it forms a wake. Depending on the blade speed and details of its geometry, this trailing edge wake can contain several different types of turbulence. Each type of trailing edge turbulence is capable of generating some sound. The energy in this sound is distributed across a wide frequency range, but it is most notable at higher frequencies between 700 Hz and 2 kHz.
- **Tip vortices:** Not all of the air entrained by a wind turbine blade flows directly over it. Because it is spinning, some of the air flows outward along the blade, and exits

the blade at its tip. The air speeds here can be quite high, and the mixing of the blade flow with the rest of the air can generate a special type of turbulence called a “tip vortex”. Like the other forms of turbulence, a small fraction of the tip vortex energy can be converted into noise. Tip vortex noise is often audible when one is near a turbine as a high-pitched whistling sound that passes with each tip: it tends to be a small component of the overall noise further away from the turbine.

Early wind turbines (designed in the 1970's) often had the blades behind the tower. As each blade in turn passed behind the tower, it encountered the tower's wind wake, a deep deficit in the airflow into the blade. This created a relatively strong blade impulse noise, sometimes referred to as a “thump”. Most modern wind turbines, like those proposed here, are built so that their rotors are located upstream of the tower. Since the blades no longer experience tower wake to the same extent, there is little to no blade impulse noise.

As a result of the turbulence-related mechanisms listed above, the majority of audible aerodynamic noise from wind turbines is broadly spread over the middle frequencies, roughly between 200 Hz and 1,000 Hz. In some unusual cases, tonal noise can originate from unstable airflows over holes, slits, or blunt trailing edges on the blades.

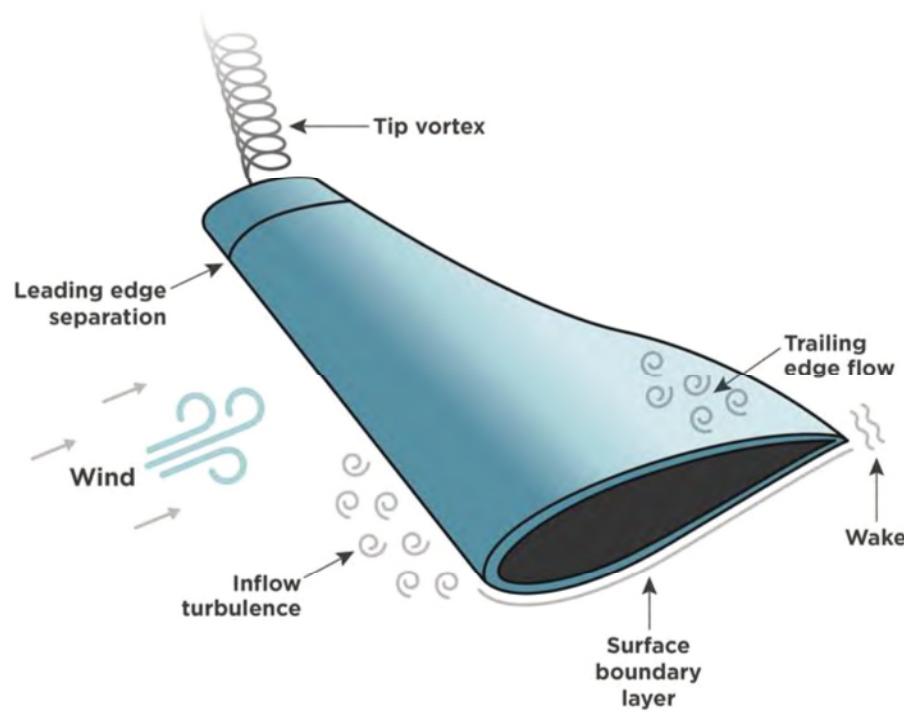

FIGURE 38: AIRFLOW AROUND A ROTOR BLADE

## MECHANICAL NOISE

As the rotor of a wind turbine turns at a relatively slow speed (a few revolutions per minute), the shaft from the rotor drives a gearbox that converts to the much higher speed (hundreds

of RPM) at which the generator must turn. Mechanical noise from the gearbox and associated machinery inside the nacelle tends to be tonal in nature but can also have a broadband component. Potential sources of mechanical noise include the gears inside the gearbox, generator, yaw drives, cooling fans, and other auxiliary equipment. This sound can escape the nacelle both via cooling vents and through its walls. However, modern wind turbine machinery is designed to generate less noise, and the nacelles are designed to better contain that noise. As a result, mechanical noise is rarely a significant contribution to the total noise emitted from an operating wind turbine.

## AMPLITUDE MODULATION

When the level of a relatively constant sound varies in a consistent manner, the effect is known as “Amplitude Modulation”, or AM. (This is the principle by which AM radio works, except that the waves are radio waves rather than sound waves.) Because the aerodynamic mechanisms of sound generation in wind turbines are moving with the blades around a very large circle, the sound received at some distance away varies at the same rate; it is perceived as being amplitude-modulated. Amplitude modulation occurs at a rate known as the Blade Passage Frequency (BPF). This frequency is the product of the number of blades times the rotor RPM divided by 60. For a relatively close observer, it is characterized by a “swish-swish-swish” sound. The amount of the fluctuation itself, expressed in dB, is known as the “modulation depth”.

Exaggerated blade swish can go by the names of “Amplitude Modulation” (AM), “Exaggerated Amplitude Modulation” (EAM), or “Other Amplitude Modulation” (OAM). There is no consistent definition of how much of a sound level fluctuation is necessary for blade swish to be considered amplitude-modulated. However, fluctuations in the A-weighted sound level from a wind turbine can reach as high as 10 dB close to the turbine. Fluctuations in individual 1/3-octave bands are typically higher and can exceed 15 dB. However, these amplitude modulation depths are relatively rare and short-lived. One recent study found 99.9 percent of modulation depth to be below 4.5 dB.<sup>3</sup> Fluctuations in individual 1/3-octave bands can sometimes synchronize and desynchronize over long periods, leading to long-term increases and decreases in the magnitude of the amplitude modulation. Similarly, in wind farms with multiple turbines, fluctuations reaching a distant observer can synchronize and desynchronize, leading to variations in amplitude modulation depth.<sup>4</sup>

Amplitude modulation of wind turbine sound has many potential causes: some have been confirmed and others remain hypothetical. These causes include: blade passage in front of the tower, the non-uniform directivity of sound emissions from the blade tip, the action of wind shear, inflow turbulence, and turbine blade yaw error. (Recently, it was reported that although wind shear can contribute to the depth of amplitude modulation, it does not cause

<sup>4</sup> McCunney, Robert, et al. “Wind Turbines and Health: A Critical Review of the Scientific Literature.” *Journal of Occupational and Environmental Medicine*. 56(11) November 2014: pp. e108-e130.

amplitude modulation in and of itself. Instead, there needs to be detachment of airflow from the blades for wind shear to contribute to amplitude modulation.<sup>5)</sup> While factors like the blade passing in front of the tower are intrinsic to wind turbine design, other factors vary with turbine design, local meteorology, topography, and the layout of multiple turbines. Amplitude modulation depth varies with the relative location of an observer to the turbine. Amplitude modulation depth is largest when the receiver is between 45 and 60 degrees away from the downwind or upwind directions; it is least when the receiver is directly upwind or downwind of a turbine.

## 5.2 | EFFECTS OF METEOROLOGY

Meteorological conditions can significantly affect how sound propagates over long distances. The two most important conditions to consider are wind shear and temperature lapse. Wind shear is the difference in wind speeds with altitude; temperature lapse rate is the change in temperature with altitude. In both cases, sound is bent, or “refracted”, away from a straight path.

In conditions with high wind shear (a large wind speed gradient), sound levels upwind from the source tend to decrease, and sound levels downwind from the source tend to increase (Figure 39).

**FIGURE 39: SCHEMATIC OF THE REFRACTION OF SOUND DUE TO VERTICAL WIND GRADIENT (WIND SHEAR)**

With temperature lapse, when ground surface temperatures are higher than those aloft, sound will tend to refract upwards, leading to lower sound levels near the ground. The opposite is true when ground temperatures are lower than those aloft: this is known as an inversion condition.

High winds and/or high solar radiation can create turbulence that tends to break up and scatter sound energy. When this occurs, sound levels are reduced more than would normally be expected with distance. Highly stable atmospheres on the other hand, which tend to occur on clear nights with low ground-level wind speeds, tend to minimize atmospheric turbulence and are generally more favorable to downwind propagation.

In general terms, sound propagates along the ground best under stable atmospheric conditions with a strong temperature inversion. This tends to occur during the night and is

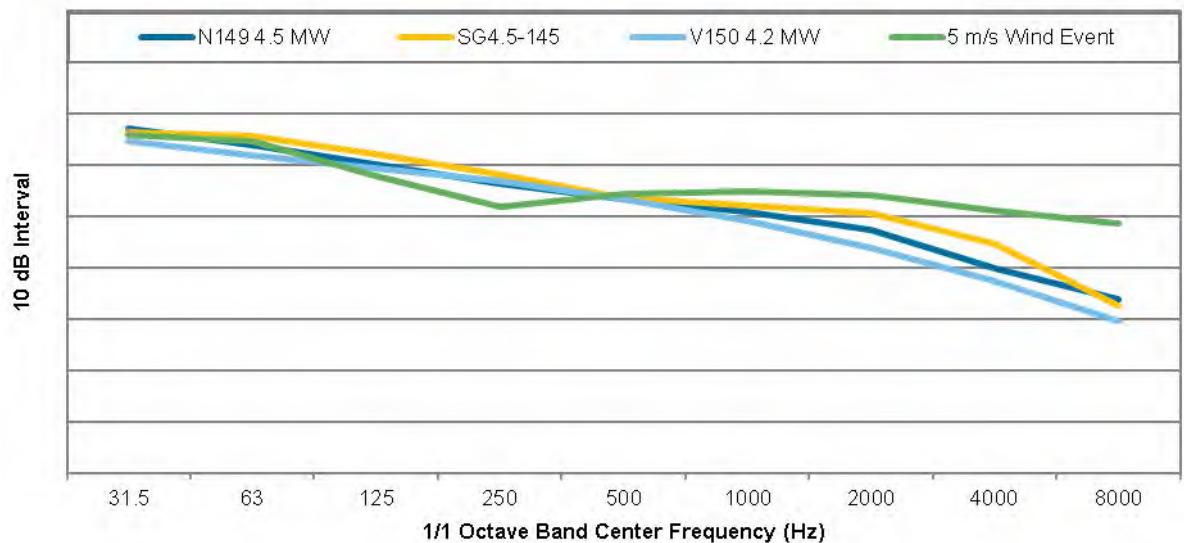

---

<sup>5</sup> “Wind Turbine Amplitude Modulation: Research to Improve Understanding as to its Cause and Effect.” *RenewableUK*. December 2013.

characterized by low ground-level winds. However, strong inversions are also often accompanied by light surface winds. As a result, worst-case conditions for wind turbines tend to occur downwind under moderate nighttime temperature inversions when wind speeds are higher. Therefore, this is the default meteorological condition assumed for modeling wind turbine sound.

### 5.3 | MASKING OF SOUND

As mentioned above, sound levels from wind turbines are a function of wind speed. Background sound is also a function of wind speed, i.e., the stronger the ground-level winds, the louder the resulting background sound. This effect is greatest in areas covered by trees and other vegetation. Wind noise itself can mask the sound from a wind turbine at downwind receivers, because the frequency spectrum from wind noise is very similar to the frequency spectrum from a wind turbine. Figure 40 compares the sound spectrum measured during a 5 m/s wind event to that generated by the Vestas V150, Siemens SG4.5-145, and Nordex N149 wind turbine. The shapes of the spectra are very similar at lower frequencies. At higher frequencies, the sounds from the masking wind noise are louder than the wind turbine. As a result, the masking of turbine noise is possible at higher ground-level wind speeds.

**FIGURE 40: COMPARISON OF NORMALIZED FREQUENCY SPECTRA MEASURED FROM A 5 M/S WIND EVENT AND THE SOUND POWER SPECTRA FROM VESTAS V150, SIEMENS SG4.5-145, AND NORDEX N149 WIND TURBINES<sup>6</sup>**

It is important to note that while winds may be blowing strongly at height of turbine hub, there may be little to no wind at ground level. This is especially true during periods with

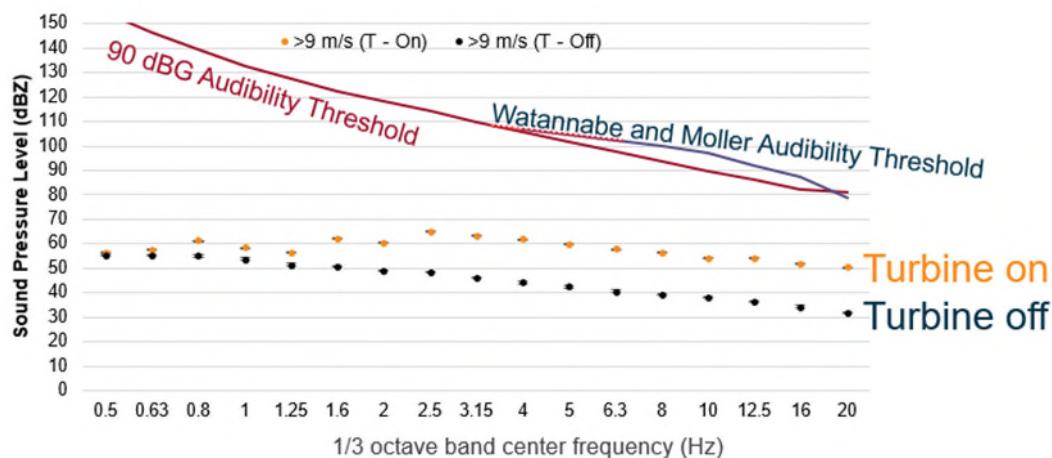

<sup>6</sup> The purpose of this Figure is to show the shapes to two spectra relative to one another and not the actual sound level of the two sources of sound.

strong wind gradients (high wind shear), which mostly occur at night. This can also occur on the leeward side of ridges where the ridge itself blocks the ground-level wind.

## 5.4 | INFRASOUND AND LOW-FREQUENCY SOUND

Infrasound is defined as any sound having its frequency content below about 20 Hz. Sound below this frequency is audible only if it has very high amplitude. Low-frequency sound is defined as being within the audible range of human hearing, that is, above 20 Hz, but below 100 to 200 Hz, depending on the application.

Low-frequency aerodynamic tonal noise is typically associated with downwind rotors on horizontal axis wind turbines, as explained in Section 5.1 above. Modern, large wind turbines have their rotor plane placed upwind of the tower. As a result, this type of low-frequency noise is of a much lower magnitude from upwind turbines than downwind turbines: it is well below established infrasonic hearing thresholds, as is shown in Figure 41. In the Figure, the curve corresponding to a sound level of 90 dBG is considered to be about 5 dB below the mean threshold of human hearing. The low-frequency sound measured at 1,150 feet from a wind turbine is 15 dB or more below the 90 dBG perceptibility curve.

**FIGURE 41: MEASURED HUMAN AUDIBILITY THRESHOLD AND THE 90 DBG CURVE (AN ASSUMED HUMAN PERCEPTION THRESHOLD) COMPARED WITH SOUND LEVEL MEASURED 350 METERS (1,150 FEET) FROM A WIND TURBINE<sup>7</sup>**

Low-frequency sound from a wind turbine is generated primarily by the generator and mechanical components. Much of the mechanical noise has been reduced in modern wind turbines through improved sound insulation in the nacelle. Low-frequency sound can also be generated by the blades when the inflow air is very turbulent, a condition more common at higher wind speeds. However, at these wind speeds, low-frequency sound generated by the wind turbine blades is often masked by ground-level wind noise at downwind receivers.

<sup>7</sup> RSG, et al., “Massachusetts Study on Wind Turbine Acoustics,” Massachusetts Clean Energy Center and Massachusetts Department of Environmental Protection, 2016 – Graphic from RSG presentation to MassDEP WNTAG, March, 2016.

Low-frequency sound is absorbed less by the atmosphere and ground than higher frequency sound. This enables it to propagate at an audible level further than higher frequency sound. (An example of this is the “clap” of thunder heard close to a lightning strike, but the “rumble” of thunder heard far from a strike.) The atmospheric propagation modeling applied to wind turbine sound accounts for frequency-specific ground attenuation and atmospheric absorption.

## 6.0 SOUND PROPAGATION MODELING

---

### 6.1 | PROCEDURES

Modeling for the project was in accordance with the standard ISO 9613-2, “Acoustics – Attenuation of sound during propagation outdoors, Part 2: General Method of Calculation.” The ISO standard states,

This part of ISO 9613 specifies an engineering method for calculating the attenuation of sound during propagation outdoors in order to predict the levels of environmental noise at a distance from a variety of sources. The method predicts the equivalent continuous A-weighted sound pressure level ... under meteorological conditions favorable to propagation from sources of known sound emissions. These conditions are for downwind propagation ... or, equivalently, propagation under a well-developed moderate ground-based temperature inversion, such as commonly occurs at night.

The model takes into account source sound power levels, surface reflection and absorption, atmospheric absorption, geometric divergence, meteorological conditions, walls, barriers, berms, and terrain. The acoustical modeling software used here was CadnaA®, from Datakustik GmbH. CadnaA® is a widely accepted acoustical propagation modeling tool, used by many noise control professionals in the United States and internationally.

ISO 9613-2 also assumes downwind sound propagation between every source and every receiver, consequently, all wind directions, including the prevailing wind directions, are considered.

Model configuration parameters are listed in Appendix B and are summarized here.

In the model, a grid of receivers<sup>8</sup> spaced 40 meters by 40 meters was set up at a height of 1.5 meters (5 feet) above the ground, covering approximately 514 sq. km. (198 sq. mi.) around the Project area.

In addition to the grid, 4,028 discrete receivers (of which 399 are participating) were included in the model, representing residences and other sensitive locations within the calculation area. Each was placed at a height of 4 meters (13 feet) above the ground. Sound levels estimated at these receivers are summarized in Appendix C for each turbine model.

The Project area was modeled acoustically as having “mixed ground” ( $G=0.5$ ), that is, half hard and half porous ground. An additional factor of 2 dB was added to the results. Foliage

---

<sup>8</sup> A receiver is a point above the ground at which the computer model calculates a sound level.

was not modeled. Taken together, these model parameters have been shown to yield conservative results in estimating a one-hour  $L_{eq}$  from wind turbines.<sup>9,10,11</sup>

Fifty turbines were modeled as sound sources. Turbines were modeled at the manufacturer's guaranteed maximum apparent sound power level. All turbine data used is the most recently available from the manufacturer at the time of this report. These sound power levels are marked as confidential by the manufacturers and are not included in the report.

Modeled spectra for the collector substation transformer and pad-mounted transformers are shown in Table 6. In each case, the sound power level is based on the NEMA TR-1 standard sound pressure level, along with data obtained from measurements of similarly-sized transformers measured by RSG.

**TABLE 3: PROJECT TRANSFORMER SOUND POWER LEVELS**

Source Description	1/1 Octave Band Sound Power (dBZ)									Sum (dBA)	Sum (dBZ)
	31.5 Hz	63 Hz	125 Hz	250 Hz	500 Hz	1 kHz	2 kHz	4 kHz	8 kHz		
Power Transformer ONAF	85	97	99	99	103	97	88	80	68	102	107
Pad Transformer	80	84	88	84	83	78	72	68	63	84	92

## 6.2 | RESULTS OF SOUND PROPAGATION MODELING

Sound propagation modeling was performed for each of three turbine models (Vestas V150 4.2 MW, Siemens SG4.5-145, and Nordex N149 4.5 MW) at all 50 potential turbine locations. The Vestas V150 4.2 MW was modeled at a 105-meter hub height, the Siemens SG4.5-145 at a 107.5-meter hub height, and the Nordex N149 4.5 MW at a 109-meter hub height.

In the instance that modeled sound levels exceeded the project's 46 dBA noise limit at Nonparticipating residences, select turbines were placed into Noise Reduced Operations (NROs).<sup>12</sup> Sound propagation modeling results under this scenario are shown in Figure 42 for the Vestas V150 4.2 MW, Figure 43 for the Siemens SG4.5-145 MW, and Figure 44 for the Nordex N149 4.5 MW. Each turbine type has its own set of NRO modes which are identified differently and result in different sound level reductions. Table 4 indicates the sound level reduction resulting from each mode in parentheses. For the Vestas turbine, the NRO modes are listed as "Sound Optimized" modes. For example, "SO1" has a sound level reduction of 1.6 dB. For the Nordex these are listed as "Modes," and Mode 0 through Mode 5 are used. For the Siemens, these modes are listed as N1 to N4 for the presented modeling.

<sup>10</sup> Bowdler, D. et al., "Prediction and Assessment of Wind Turbine Noise: Agreement about Relevant Factors for Noise Assessment from Wind Energy Projects." Acoustics Bulletin. 34(2), pp. 35-37.

<sup>11</sup> Evans, T. and Cooper, J., "Comparison of Predicted and Measured Wind Farm Noise Levels and Implications for Assessments of New Wind Farms." Acoustics Australia: April 2012. Vol. 40, No. 1.

<sup>12</sup> Noise Reduced Operations modes are turbine modes that reduce the maximum sound power emissions of turbines. This is typically accomplished through slowing down the rotational speed of the turbine's rotor.

The results show that Project-only sound levels in each of these three mitigated scenarios do not exceed 46 dBA at any Nonparticipating residence.

Note that particular turbine locations that are in NRO may change due to modifications to turbine locations, the final number of turbines built, and changes in manufacturer-published turbine sound emissions data. Specific NRO plans may include provisions for different NRO settings to be used depending on the time of day and meteorological conditions. The total number of turbines in each NRO mode are summarized in Table 4.

**TABLE 4: NUMBER OF TURBINES IN EACH NOISE MODE**

Vestas V150 4.2 MW		Siemens SG4.5-145		Nordex N149 4.5 MW	
Operational Mode	Turbine Count	Operational Mode	Turbine Count	Operational Mode	Turbine Count
Full Sound Power	47	Full Power	20	Mode 0	41
SO1 (1.6 dB)	3	N1 (2 dB)	18	Mode 1 (0.6 dB)	2
-	-	N2 (2.5 dB)	7	Mode 2 (1.1 dB)	1
-	-	N3 (4 dB)	4	Mode 3 (1.5 dB)	1
-	-	N4 (5 dB)	1	Mode 4 (2 dB)	4
-	-	-	-	Mode 5 (2.5 dB)	1

## CONSTRUCTION ACTIVITY SOUND EMISSIONS

Wind turbine construction will be primarily at the turbine sites. While there may be activity closer to residences for road construction and utility work, such work will have a relatively short duration.

Equipment used for construction will vary. Some of the louder pieces of equipment are shown in Table 5 along with the approximate maximum sound pressure levels at 50 feet (15.2 m) and 1,471 feet (448 meters), the closest distance between a turbine site and a nonparticipating residence.

**TABLE 5: MAXIMUM SOUND LEVELS FROM VARIOUS TYPES OF CONSTRUCTION EQUIPMENT ASSUMING NO ATTENUATION FROM TREES OR TERRAIN**

Equipment	Maximum Sound Pressure Level at 448 meters (1,471 feet) (dBA) <sup>13</sup>	Maximum Sound Pressure Level at 15 meters (50 feet) (dBA)
M-250 Liftcrane	48	83
2250 S3 Liftcrane	43	78
Excavator	50	83
Dump truck being loaded	54	86
Dump truck at 25 mph accelerating	44	76
Tractor trailer at 25 mph accelerating	49	80
Concrete truck	46	81
Bulldozer	50	85
Rock drill	62	100
Loader	42	80
Backhoe	45	80
Wood chipper	64	96

Major construction work, such as clearing for the access roads and any drilling and blasting, will occur during the day. Per OPSB requirements, any construction activities that increase sound above ambient levels at sensitive receptors will be limited to the hours of 7 AM to 7 PM or dusk, whichever is later. Pile driving, blasting, and rock hammering will occur between the hours of 10 AM to 5 PM.

---

<sup>13</sup> Assumes hard ground around construction site, and ISO 9613-2 propagation with no vegetation reduction. Actual sound levels will likely be lower given the prevalence of vegetation and soft ground around the site.

## 7.0 SUMMARY AND CONCLUSIONS

---

The Republic Wind Project is a wind power project located in an area straddling the border between Seneca County and Sandusky County, Ohio, between the towns of Republic and Bellevue. In preparation for Ohio Power Siting Board (OPSB) permitting, Apex Clean Energy retained RSG to perform background sound level monitoring of the existing environment in and around the project area and sound propagation modeling to predict project-only sound levels at nearby residences. RSG previously published a report for this project (*Noise Impact Assessment for Republic Wind*, December 22, 2017), with a turbine array that included up to 58 turbines. The current report summarizes modeling results from an alternative array with up to 50 locations, with one spare location, for three additional turbine model options. Summary and conclusions are as follows:

- Republic Wind with this turbine array is proposed to include up to 50 turbine locations. Currently three additional turbine models are being considered: the Vestas V150 4.2 MW with a 150-meter diameter rotor and a 105-meter hub height, the Siemens/Gamesa SG4.5-145 with a 145-meter diameter rotor and a hub height of 107.5 meters, and the Nordex N149 4.5 MW with a 149-meter diameter rotor and a 109-meter hub height. Each turbine will include a pad-mounted transformer at its base and the collector substation will include a single 67-90-112 MVA transformer.
- The sound level limit specified in Ohio Administrate Code Section 4906-4-09(F) has set the applicable nighttime noise limit at a home to 5 dBA above the facility area nighttime ambient sound levels ( $L_{eq}$ ).
- Background sound level monitoring was performed at seven locations throughout the project area. Daytime and nighttime equivalent continuous sound levels ( $L_{eq}$ ) ranged from 37 to 52 dBA and 32 to 51 dBA respectively. Daytime and nighttime lower tenth-percentile sound levels ( $L_{90}$ ) ranged from 23 to 32 dBA and 17 to 27 dBA respectively.
- The facility average nighttime sound level is 41 dBA, resulting in a noise limit for the Project of 46 dBA, based on the OAC limits.
- Sound propagation modeling was performed in accordance with international standard ISO 9613-2 at 4,028 discrete receivers that surround the project. Modeling was performed assuming half hard and half porous ground ( $G=0.5$ ) and an additional 2 dB uncertainty factor was added to the results.
- With noise reduced operations applied to some turbine locations, the highest sound level modeled at a Nonparticipating receiver was 46 dBA, with all Nonparticipating receivers at or below the nighttime background  $L_{eq}$  plus 5 dB of 46 dBA.
- Other than extended concrete pours and similar events, major construction will take place during normal business hours. Construction activities that increase sound above ambient levels at sensitive receptors will be limited to the hours of 7 AM to 7

PM or dusk, whichever is later. Aside from road construction, these activities will take place at over 1,471 feet (448 meters) from the nearest residences.

## APPENDIX A: A PRIMER ON SOUND AND NOISE

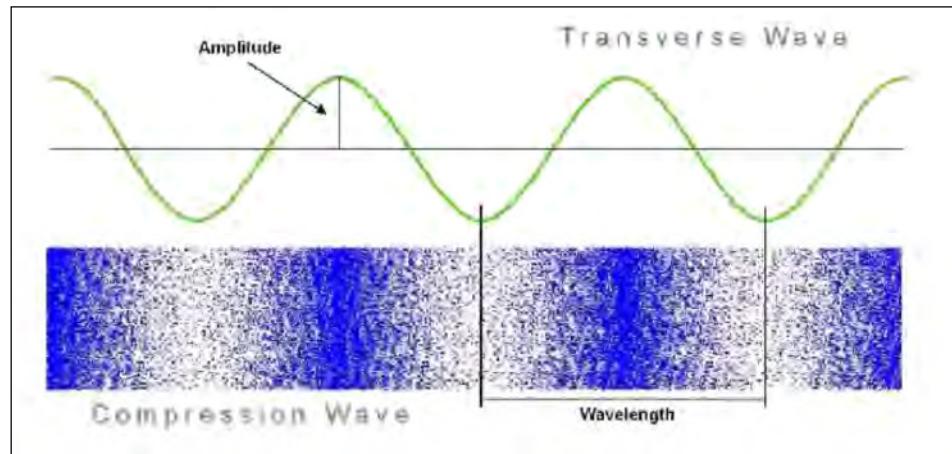

This report will use a variety of terms used to describe sound levels. Since sound can have many characteristics, there are many different ways to describe sound.

### A.1 | SOUND AS A WAVE

Sound is the rapid oscillation of particles in any medium. Using this definition, the sound we experience day-to-day is the rapid vibration of air that we can sense with our ears. However, sound can also propagate through solids such as steel, rock, or wood and through liquids such as water.

Through air, sound propagates as a compression wave. That is, sound travels as fluctuations of air pressure above and below the atmospheric pressure. Sound can also be described in terms of vibrating of air particles where, at certain points along the wave, air particles are compressed and, at other points, the air particles are spread out.

Figure 45 illustrates two ways of describing sound. The blue section at the bottom shows an example of a compression wave, with air particles represented in blue. The green at the top of the figure shows a transverse wave. A transverse wave is similar to a vibrating string. While sound does not physically propagate as a transverse wave, the transverse wave can be used to describe the two main properties of waves in general: amplitude and wavelength.

**FIGURE 45: SOUND AS A WAVE**

In reference to sound, amplitude is what we perceive as the sound pressure level or how loud a source is. The higher the amplitude of the sound wave, the louder it is. Physically, sound amplitude is a measure of the extent to which the air pressure, due to a sound wave, fluctuates above and below atmospheric pressure. In terms of the compression wave shown in Figure 45, amplitude is expressed by how compressed or spread out the air particles are at the various points along the sound wave.

Wavelength is the distance between two maximum compression locations in a sound wave. One wavelength is one complete cycle of the sound wave. Wavelength is important because it is directly related to the frequency of the sound, which is what the human ear perceives as pitch. Sound with longer wavelengths are lower in frequency, and shorter wavelengths are higher in frequency. Frequency is dealt with in greater depth in Section A.3 | Spectral Sound Levels.

## A.2 | SOUND PRESSURE LEVEL

The level of a sound is typically quantified by the pressure it exerts. The air pressures from sound that humans can hear range from  $20 \mu\text{Pa}$  to over  $10,000,000 \mu\text{Pa}$ . In order to scale the range down and better approximate the human perception of relative loudness, we use a logarithmic scale for sound pressure level. The unit used for the logarithmic scale is the decibel (dB).

The lower threshold of human hearing is 0 dB at 1000 Hz and the threshold of pain is around 130 dB. A typical conversation in a room is between 50 and 60 dBA (“dBA” indicates that these levels are A-weighted. A-weighting is discussed in Section A.3 | Spectral Sound Levels).

Sound is difficult to describe in individual instantaneous measurements, which gives the sound pressure level at an exact moment in time. The level reading could be 62 dB, but a second later it could 57 dB. Sound pressure levels are constantly changing. It is for this reason that it makes sense to describe sound levels over time.

Take as an example, the sound levels measured over time shown in Figure 46. Instantaneous measurements are shown as a ragged grey line. The sound levels that occur over this time can be described verbally, but it is much easier to describe the recorded levels statistically. This is done using a variety of “levels” which are described below.

### LMIN AND LMAX

Lmin and Lmax are simply the minimum and maximum sound level, respectively, monitored over a period of time. Note that “maximum” is not the same as “peak”. Peak levels have a different meaning, which is more applicable to sounds which can create hearing damage, which is not dealt with here.

### PERCENTILE SOUND LEVEL - LN

Ln is the sound level exceeded n percent of the time. This type of statistical sound level, also shown in Figure 46, gives us information about the distribution of sound levels. For example, the L10 is the sound level that is exceeded 10 percent of the time, while the L90 is the sound level exceeded 90 percent of the time. The L50 is the median and is exceeded half the time. The L90 is often described as the “residual” level, describing a condition when most short-term contaminating sources are removed.

## EQUIVALENT CONTINUOUS SOUND LEVEL - LEQ

One of the most common ways of describing noise levels is in terms of the equivalent continuous sound level ( $L_{eq}$ ). The  $L_{eq}$  is the average of the sound *pressure* over an entire monitoring period and expressed as a decibel:

$$Leq_T = 10 * \log_{10} \left( \frac{1}{T} \int_0^T p_A^2(t) dt / p_0^2 \right)$$

where  $p_0^2$  is the squared instantaneous weighted sound pressure signal, as a function of elapsed time  $t$ ,  $p_0$  is the reference pressure of  $20\mu\text{Pa}$ , and  $T$  is the stated time interval.

The monitoring period,  $T$ , can be for any amount of time. It could be one second ( $L_{eq\ 1\text{-sec}}$ ), one hour ( $L_{eq(1)}$ ), or 24 hours ( $L_{eq(24)}$ ). Because  $L_{eq}$  is a logarithmic function of the average pressure, loud and infrequent sounds have a greater effect on the resulting  $Leq$  than quieter and more frequent sounds. For example, in Figure 46, the  $L_{50}$  (median) is about 47 dB, but the  $L_{eq}$  is 53 dB. Because it tends to weight the higher sound levels and is representative of sound that takes place over time, the  $L_{eq}$  is the most commonly used descriptor in noise standards and regulations.

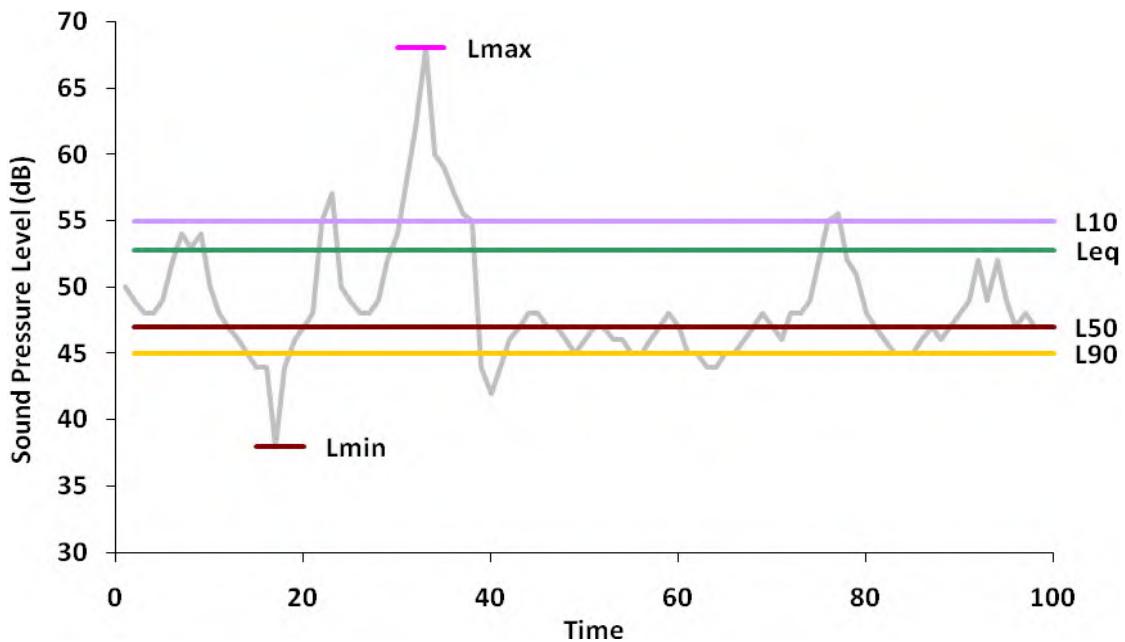

FIGURE 46: EXAMPLE OF DESCRIPTIVE TERMS OF SOUND MEASUREMENT OVER TIME

### A.3 | SPECTRAL SOUND LEVELS

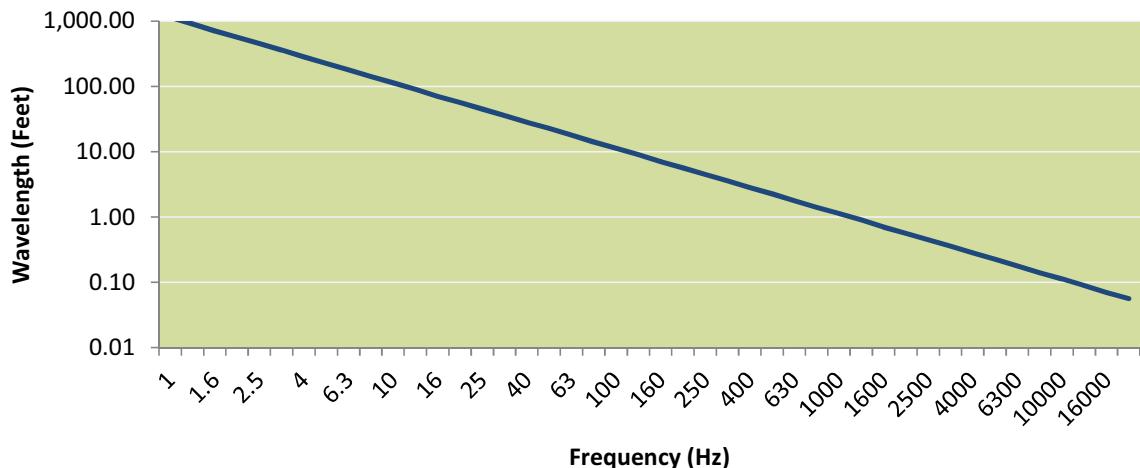

As previously stated, frequency is inversely related to wavelength. The unit used for frequency is cycles per second or hertz (Hz). The relationship between wavelength and frequency is dependent on the speed of sound.

$$\lambda = \frac{c}{f}$$

where  $\lambda$  is wavelength,  $c$  is the speed of sound, and  $f$  is frequency.

Figure 47 shows corresponding wavelengths and frequencies for sound in air at 68°F. People can generally hear sounds at frequencies between 20 and 20,000 Hz (also designated as 20 kHz). As shown, wavelengths in the range of human hearing vary considerably from 56 feet at 20 Hz, to less than an inch at 20 kHz.

Sound below 20 Hz is known as infrasound. Sometimes, we can perceive frequencies below 20 Hz, but that is typically due to our sense of vibration rather than hearing or if the levels are very high. Infrasound wavelengths are very long, with sound at 1 Hz having a wavelength of just over 1,000 feet. Sound above 20 kHz is called ultrasound and is not perceptible by the human ear.

**FIGURE 47: RELATIONSHIP BETWEEN FREQUENCY AND WAVELENGTH**

Most sources are complex and composed of a wide range of frequencies at different sound levels. The range of frequencies and their corresponding sound levels is called a frequency spectrum.

Some sources are tonal, like the individual notes on a piano. Others are broadband, like fans. Human speech typically occurs between 200 Hz and 5 kHz.

## OCTAVE BANDS

For analysis purposes, sound is typically broken down into different frequency divisions, or bands. The most common division is the standard octave band. An octave is a band of frequencies whose lower frequency limit is half of the upper frequency limit. An octave band is identified by its center frequency. As an example, the 500 Hz octave band contains all frequencies between 360 Hz and 720 Hz. An octave higher would be twice this. That is, it would be centered at 1,000 Hz with a range between 720 and 1,440 Hz. The range of human

hearing is divided into 10 standardized octave bands: 31.5 Hz, 63 Hz, 125 Hz, 250 Hz, 500 Hz, 1 kHz, 2 kHz, 4 kHz, 8 kHz, and 16 kHz. For analyses that require even further frequency detail, each octave band is often broken down into parts, such as 1/3 octave bands.

## FREQUENCY WEIGHTING

As previously mentioned, sound pressure levels are expressed in terms of decibels. Since the human ear is not sensitive to all frequencies equally, some frequencies, despite being the same decibel level, seem louder than others. For example, a 500 Hz tone at 80 dB sounds louder than a 63 Hz tone at 80 dB. For this reason, frequency weightings are applied to sound levels (Figure 48). The most common weighting scale used in environmental noise analysis is the A-weight, which more accurately represents the sensitivity of the human ear at low to moderate sound energy. An A-weighted sound level is usually denoted with the unit dBA or dB(A).

The C-weighting is often used for high-energy sounds such as explosions. It weights low-frequency sounds more than the A-weighting. The Z-weighting is used to designate no weighting.

Recently, a new weighting has been proposed – the Ai weighting.<sup>14</sup> This is the A-weighted sound level with all sound above 1,250 Hz eliminated. This weighting is intended to be used to filter out biogenic sound that occurs at high frequencies, such as insects and birds.

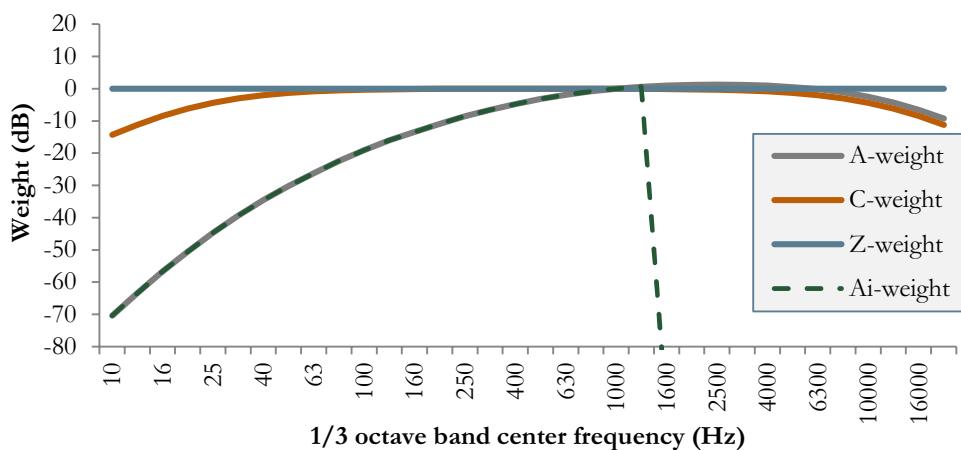

FIGURE 48: SOUND WEIGHTING SCHEMES

<sup>14</sup> Schomer Paul, D.; Slauch Ian, M.; Hessler George, F, “Proposed "Ai"-weighting; A weighting to remove insect noise from A-weighted field measurements”, INTER-NOISE and NOISE-CON Congress and Conference Proceedings, InterNoise10, Lisbon PORTUGAL, pages 3543-4457 pp. 3991-4000(10)

## A.4 | SOUND LEVEL METER RESPONSE

As noted in Section 0.2, sound levels vary over time. In fact, the variation is so fast, that one would not be able to reliably read the level on a sound level meter. For that reason, the level shown on sound level meters is often subject to exponential time response, which dampens the reading showed on the meter display to make it readable.

There are three responses available on most sound level meters: slow, fast, and impulse. These levels are denoted as  $L_s$ ,  $L_f$ , and  $L_i$ , respectively. These may also be designated with a weighting, such as  $LA_f$  for A-weighted fast –response level. Fast response has a time constant of 125 ms. This response is similar to the response of the human ear. The slow response has a time constant of 1 second. This is often used in environmental noise measurement in that it has a slow rise and fall time, which eliminates very short spikes in noise that are not related to the measurement. The impulse response has a very fast rise time of 35 ms and a slow decay time of 1.5 seconds. It is rarely used in environmental noise measurements, but can be used with other metrics to evaluate the impulsivity of a sound event.

Fast, slow, and impulse sound levels cannot be averaged, since they are not representative of the actual sound level over time – they are simply applied to the actual sound level to slow the meter reading. So, an integration of fast, slow, or impulse sound levels will not give an accurate representation of the energy average sound level over time. However, percentiles can be used when this is needed. A true energy average, or equivalent average sound level can be calculated using the  $Leq$  metric, which is independent of the sound level meter response setting.

## APPENDIX B: SOUND SOURCE INFORMATION

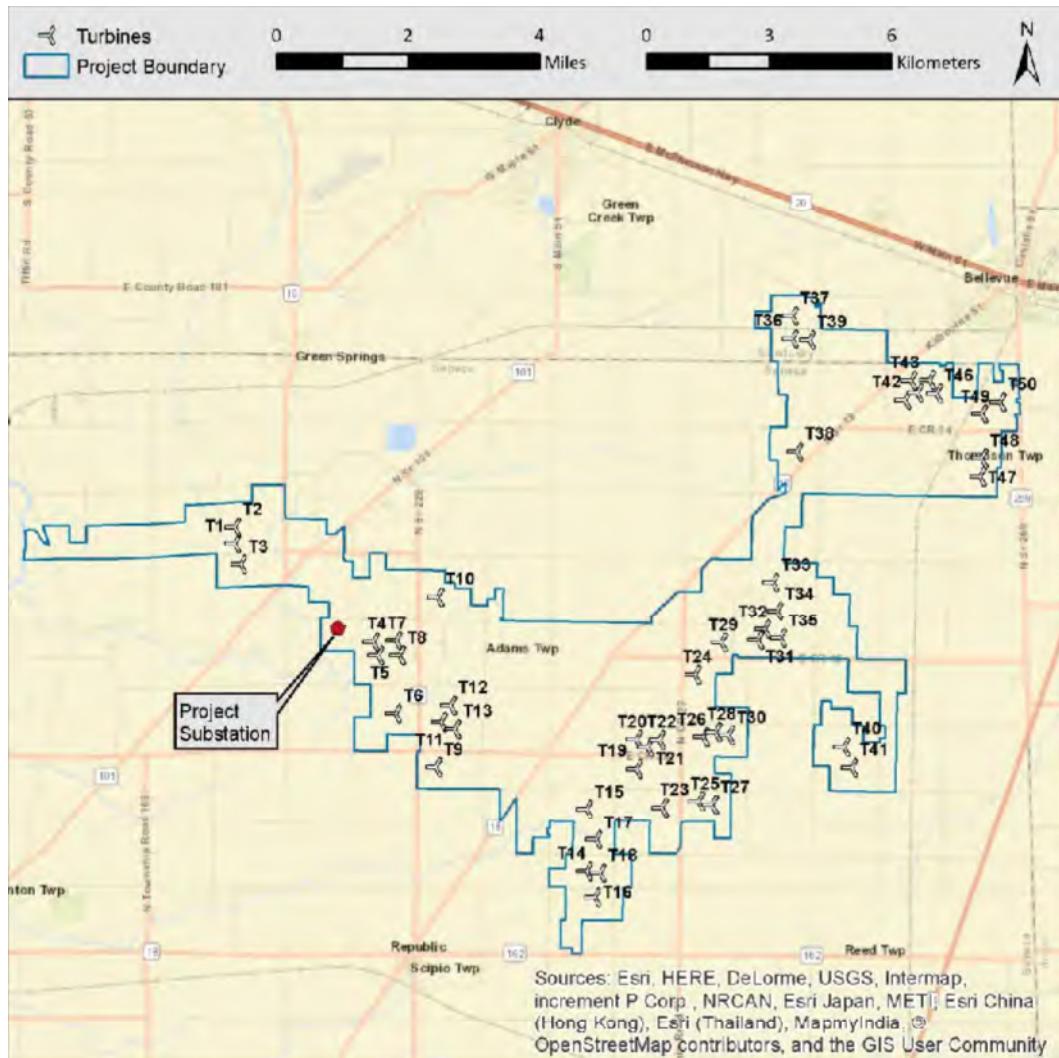

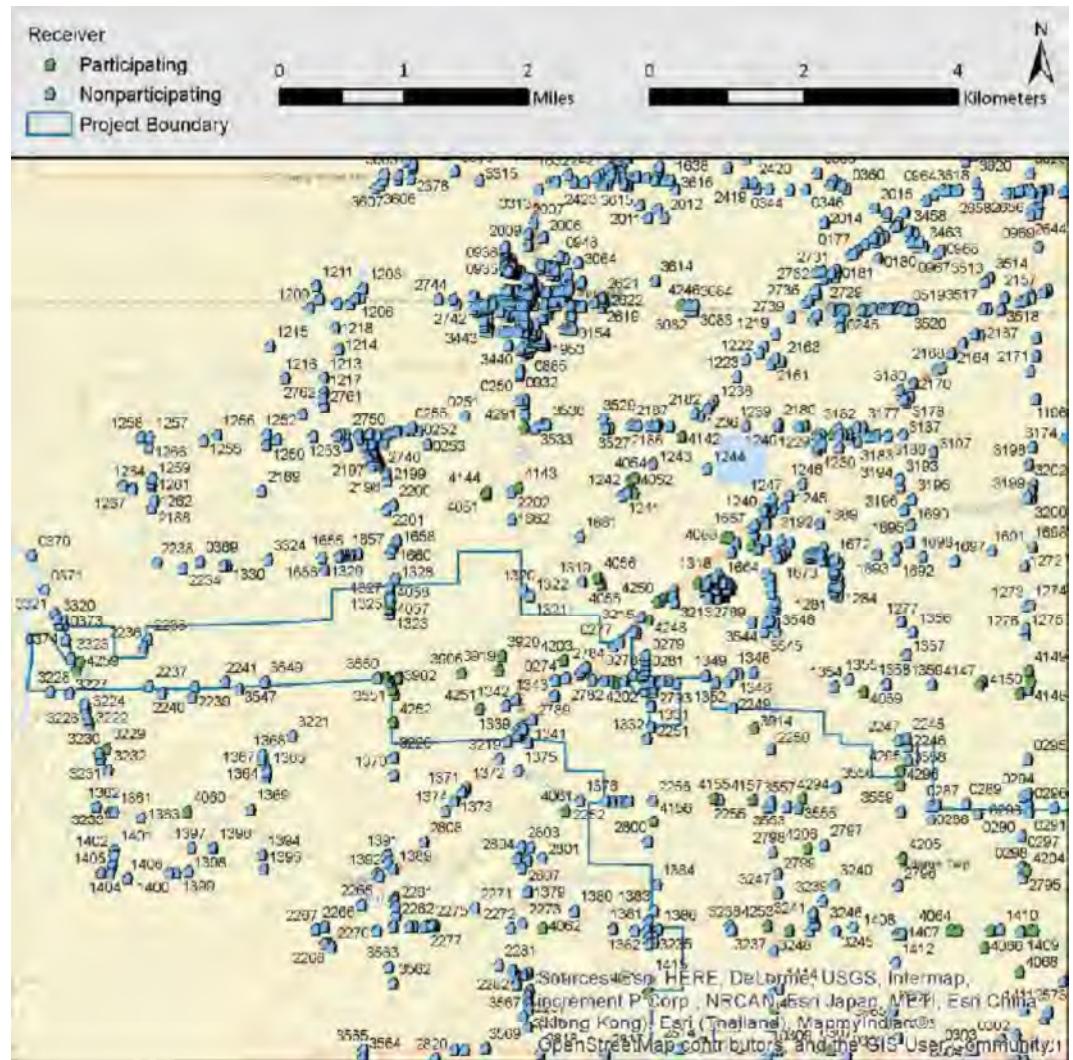

FIGURE 49: SOUND SOURCE MAP

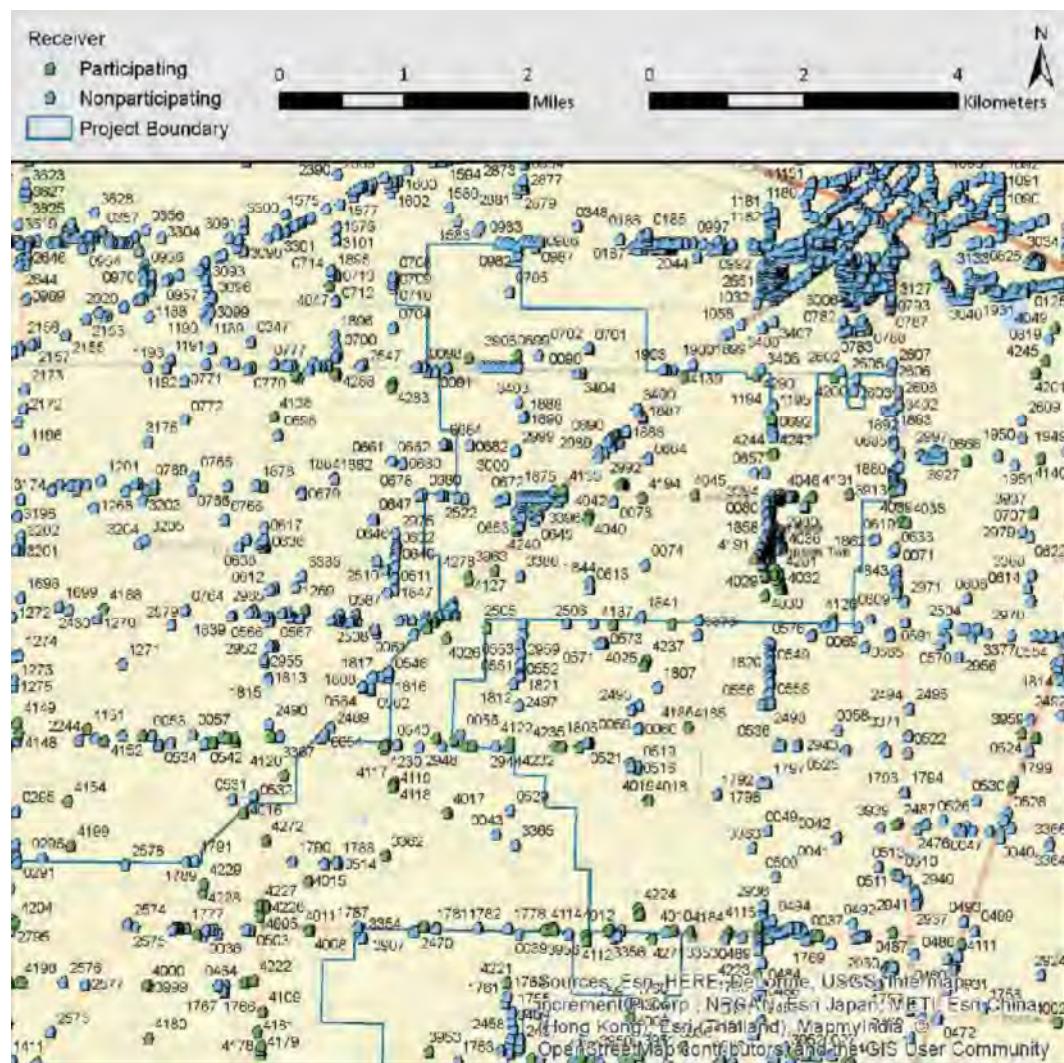

TABLE 6: SOUND PROPAGATION MODELING PARAMETERS

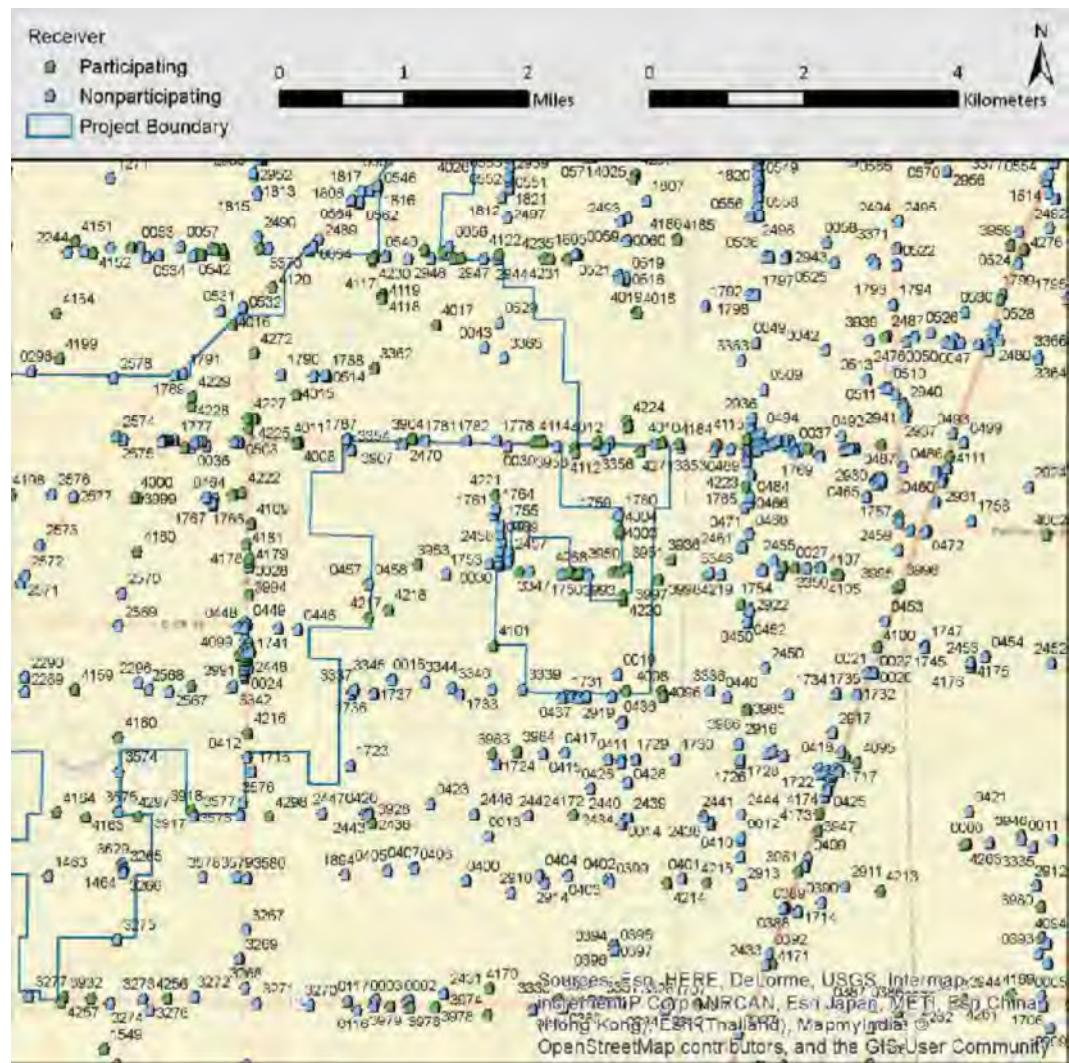

Parameter	Setting
Ground Absorption	Spectral for all sources, Mixed Ground (G=0.5)
Atmospheric Attenuation	Based on 10 Degrees Celsius, 70% Relative Humidity
Reflections	None
Receiver Height	4 meters for residences, 1.5 meters for grid
Search Distance	8,000 meters
