1.0 INTRODUCTION

Seneca Wind LLC (Seneca Wind) is proposing to develop the Seneca Wind project (the Project), a wind energy facility located in Seneca County, Ohio. The original analysis, prepared in July 2018, analyzed 94 potential turbine locations, 10 of which were General Electric (GE) GE 2.3-116 wind turbines and the remaining turbines comprised of GE 2.5-127 wind turbines, of which only 85 turbines were proposed to be constructed. In September 2018, an update was prepared to reflect that the positions studied for GE 2.5-127 turbines could alternately be built with Siemens Gamesa (SG) 2.7-129 model turbines. In January 2019, an update was prepared to decrease the hub height for the SG 2.7-129 to 109 meters (m) (357.6 feet) and incorporate a shift in the location of Turbine 59 by approximately 50 feet (15.24 feet). The January 2019 update was based on use of 10 GE 2.3-116 wind turbines, and the remainder were proposed to be either GE 2.8-127 or SG 2.7-129 wind turbines. In addition, the January 2019 update reflected removal of one turbine to accommodate the Project substation, resulting in a total of 93 potential turbine locations. Because output from the turbines increased, the total number of turbines that would ultimately be constructed was limited to 77.

This update reflects the introduction of the Vestas (V) 110-2.2 wind turbine model, as well as the utilization of the GE 2.3-116 turbines at additional locations or at different hub heights. The Project, as evaluated in this report, includes six potential turbine model layout design scenarios, which are described in detail in Attachment A.

The wind turbines being considered have the following characteristics:

- **GE 2.3-116** – A 3-blade 116-m (380.6 feet) rotor diameter and generating capacity of 2.3 MW. Up to 26 GE 2.3-116 turbines will be used. These turbines would have a hub height of either 80 m (262.5 feet), 90 m (295.3 feet), or 94 m (308.4), depending on the location and layout scenario.
- **GE 2.8-127** – A 3-blade 127-m (416.7 feet) rotor diameter and generating capacity of 2.82 MW. Up to 67 GE 2.8-127 turbines would be used. This turbine would have a hub height of 114 m (374.0 feet). It is possible that 112 m (367.5 feet) towers may be used in a few select locations to address location-specific issues.
- **SG 2.7-129** – A 3-blade 129.69-m (425.5 feet) rotor diameter and generating capacity of 2.7 MW. Up to 67 SG 2.7-129 turbines may be used as an alternative turbine to the GE 2.8-127. This turbine would have a hub height of 109 m (357.6 feet).
- **V110-2.2** – A 3-blade 110-m (360.9 feet) rotor diameter and generating capacity of 2.2 MW. Up to 10 V110-2.2 turbines may be used as an alternative to the GE 2.8-127 or the SG 2.7-129. This turbine would have a hub height of 95 m (311.7 feet).

Although a total of 93 turbine locations, as shown in Figure 1, have been assessed, only a maximum of 77 turbines will be constructed. This provides conservative results, as the effect of shadow flicker in some locations could be reduced if a contributing turbine is not constructed.

2.0 SHADOW FLICKER BACKGROUND

A wind turbine's moving blades can cast a moving shadow on locations within a certain distance of a turbine. These moving shadows, called shadow flicker, are a temporary phenomenon experienced near the turbines; the effect decreases with distance. The impact area depends on the time of year and day (which determine the sun's azimuth and altitude angles) and the wind turbine's physical characteristics (height, rotor diameter, blade width, and orientation of the rotor blades). Shadow flicker impact to surrounding properties generally occurs during low angle sunlight conditions, which typically occur during sunrise and sunset. However, when the sun angle gets very low (less than 3 degrees), sunlight passes through more of the atmosphere and becomes too diffused to form a coherent shadow (i.e., would not be perceived as flash). Shadow flicker will also not occur when the sun is obscured (e.g., by clouds or fog or at night) or

when the source turbine(s) are not operating. In addition, shadow flicker is only an issue when at least 20 percent of the sun's disc is covered by the turbine blades.

Shadow flicker intensity is defined as the difference in brightness at a given location in the presence and absence of a shadow. Shadow flicker intensity diminishes with greater receptor-to-turbine separation distance. Shadow flicker intensity for receptor-to-turbine distances beyond 2,500 m (8,202 feet) is very low, and generally considered imperceptible. In general, shadow flicker may be more noticeable in closer proximity to turbines, with the largest number of shadow flicker hours, along with greatest shadow flicker intensity, occurring in locations closest to the wind turbines.

Shadow flicker frequency is related to the wind turbine's rotor blade speed and the number of blades on the rotor. From a health standpoint, the low flicker frequencies associated with wind turbines are harmless, and public concerns that flickering light from wind turbines can have negative health effects, such as triggering seizures in people with epilepsy, are unfounded. Epilepsy Action (the working name for the British Epilepsy Foundation) states that there is no evidence that wind turbines can cause seizures (Epilepsy Action 2018). However, they recommend that wind turbine flicker frequency be limited to 3 Hertz (Hz); for comparison, strobe lights used in discos have frequencies which range from about 3 Hz to 10 Hz (1 Hz = 1 flash per second). Since the Project's wind turbine blade pass frequency is approximately 0.8 Hz (less than 1 blade pass per second), no negative health effects to individuals with photosensitive epilepsy are expected.

The Ohio Power Siting Board (OPSB) has established specific standards for shadow flicker related to wind energy facilities in Ohio Administrative Code (OAC) 4906-4-09(H)(1). This regulation requires that applicable facilities, such as the Project, be designed to avoid unreasonable adverse shadow flicker effect at any non-participating sensitive receptor within 1,000 m (3,280.8 feet) of any turbine and establishes shadow flicker levels of 30 hours per year as a minimum threshold for determining impacts. This metric has been used as a benchmark for the shadow flicker analysis.

3.0 WINDPRO SHADOW FLICKER ANALYSIS

An analysis of potential shadow flicker impacts from the Project was conducted using the WindPro software package. As described above, 93 turbine locations have been evaluated with WindPro, although only up to 77 wind turbines would be installed.

The WindPro analysis was conducted to determine shadow flicker impacts under realistic impact conditions (actual expected shadow). This analysis calculated the total amount of time (hours and minutes per year) that shadow flicker could occur at receptors surrounding the Project. The realistic impact condition scenario is based on the following:

- The elevation and position geometries of the wind turbines and surrounding receptors (potentially occupied residences). Elevations were determined using United States Geological Survey digital elevation model data. Position geometries were determined using geographic information system and referenced to Universal Transverse Mercator Zone 17 (North American 1983 Datum [NAD83]).
- The position of the sun and the incident sunlight relative to the wind turbine and receptors on a minute-by-minute basis over the course of a year (WindPro-generated values).
- Historical sunshine availability (percent of total hours available). Historical sunshine rates for the area, as summarized by the National Climatic Data Center (National Oceanic and Atmospheric Administration [NOAA] 2016) for nearby Toledo, Ohio, used in this analysis are as follows:

- January – 41 percent
 - February – 48 percent
 - March – 50 percent
 - April – 53 percent
 - May – 59 percent
 - June – 61 percent
 - July – 65 percent
 - August – 61 percent
 - September – 58 percent
 - October – 52 percent
 - November – 34 percent
 - December – 29 percent
- Estimated wind turbine operations and orientation (based on over 8 years of wind data from October 2009 through June 2018, including wind speed/wind direction, frequency, and distribution, measured at meteorological towers located in the Project area).
 - Receptor viewpoints (i.e., house windows) are assumed to always be directly facing turbine-to-sun line-of-sight (“greenhouse mode”).

WindPro incorporates terrain elevation contour information, and the analysis accounts for terrain elevation differences. The sun's path with respect to each turbine location is calculated by the software to determine the cast shadow paths every minute over a full year. Sun angles less than 3 degrees above the horizon were excluded for the reasons identified in Section 2. Since shadow flicker is only an issue when at least 20 percent of the sun disc is covered by the blades, WindPro uses blade width dimension data to calculate the maximum distance from the turbine where shadow flicker must be calculated. Beyond this distance, the turbine will not contribute to the shadow flicker impact. No potential screening effect from trees, shrubs, barns, or other obstacles was assumed in the shadow flicker analysis. In reality, such factors can block shadows from falling onto windows of receptors and eliminate the effect, therefore, this analysis represents a conservative estimate of shadow flicker impact.

A total of 2,902 structures were identified within 1 mile of the Project Area and were assumed to be occupied or potentially occupied residences (receptors for the purpose of this analysis). A receptor in the model is defined as a 1 square meter area (the approximate size of a typical window) that is located 1 m (3.28 feet) above ground level. Approximate eye level is set at 1.5 m (4.94 feet). Figure 1 shows the locations of all 2,902 shadow flicker receptors (presumed to be occupied residences), along with the 93 potential turbine locations evaluated.

4.0 SHADOW FLICKER ANALYSIS RESULTS

As expected, WindPro predicts that shadow flicker impacts will be greatest at locations nearer to the wind turbines. Figures 2 through 7 illustrate the WindPro-predicted shadow flicker impact areas for turbine scenarios 1 through 6, respectively. A detailed WindPro shadow flicker analysis summary, for each turbine model scenario and the modeled receptor locations, is provided in Attachment B.

Table 1 presents the WindPro predicted shadow flicker impacts for the 48 receptors (of 2,902 total receptors) for which potential impacts were calculated as being over 30 hours per year. Of these receptors, 26 have entered into agreements with Seneca Wind, and are considered participating landowners. Table 1 presents the worst-case impacts from any of the six turbine model scenarios modeled.

The shadow flicker impact prediction statistics are summarized in Table 2. The predicted shadow flicker impacts for the 22 non-participating residences range from 60 hours, 31 minutes per year (at Receptor 76) to 30 hours, 1 minute (at Receptor 117). Even the highest predicted shadow flicker impact (60 hours and 31 minutes) reflects only approximately 1.4 percent of annual daylight hours.

Seneca Wind is committed to reducing shadow flicker impacts to meet the OPSB requirements. For each of the 22 non-participating residences that currently exceed that standard, additional investigation and/or coordination will occur to determine the most effective approach if leases with affected non-participating

landowners cannot be acquired. This may include refined analyses that incorporate the potential for vegetation to block line-of-sight and/or to refine window exposures; and consideration of mitigation measures such as window shades or other screening measures. As decisions are made regarding which specific turbine locations will be constructed, flicker modeling may be revised, as contributing turbines (if those locations are not to be constructed) may be skewing the results higher than would actually be experienced. If necessary, curtailed operation under certain conditions can also be considered.

5.0 CONCLUSION

The analysis of potential shadow flicker impacts from the Project on nearby receptors shows that shadow flicker impacts within the area of study are expected to be minor, although for 22 non-participating receptors impact potential exceeds the OPSB standard of 30 hours per year. The highest level of impact for non-participating receptors reflects impacts occurring just 1.4 percent of annual daylight hours, as compared to the 0.7 percent of annual daylight hours reflected by 30 hours per year. This small incremental difference is not expected to be significant. However, as noted above, Seneca Wind is committed to achieving compliance with the OPSB standard and will conduct additional investigations and/or coordination to identify the most effective and appropriate approach, if leases with affected non-participating landowners cannot be acquired.

The analysis was deliberately conservative and actual shadow flicker is expected to occur at lower rates than modeled. The analysis assumes that the receptors all have a direct in-line view of the incoming shadow flicker sunlight and does not account for trees or other obstructions which may block sunlight. Impacts will also be reduced given that the windows of many houses will not face the sun directly during the key shadow flicker impact times. Adding to the conservative approach reflected in these results, the 93 turbines were modeled cumulatively; however, because Seneca Wind will only construct up to 77 turbines, some turbines that contribute to potential shadow flicker effects at certain residences will be eliminated, reducing or eliminating the potential for impact.

1.0 INTRODUCTION

Seneca Wind LLC (Seneca Wind) is proposing to develop the Seneca Wind project (the Project) located in Seneca County, Ohio. The original analysis, prepared in July 2018, analyzed 94 potential turbine locations, 10 of which were General Electric (GE) GE 2.3-116 wind turbine models and the remaining turbines comprised of GE 2.5-127 wind turbine models; a total of only 85 turbines would be the maximum number to be constructed. In September 2018, an update was prepared to reflect that the GE 2.5-127 turbines might be substituted with the Siemens Gamesa (SG) 2.7-129 model turbines. In January 2019, an update was prepared to decrease the hub height for the SG 2.7-129 to 109 meters (m) (358 ft) and incorporate a shift in the location of Turbine 59 by approximately 15.24 m (50 ft). The January 2019 update was assumed that 10 turbines would be GE 2.3-116 wind turbines, and the remainder would be either GE 2.8-127 or SG 2.7-129 wind turbines. The total number of turbine locations were also reduced to 93. Because output from the turbines increased, the total number of turbines that would ultimately be constructed was limited to 77.

This latest update reflects the introduction of the Vestas (V) 110-2.2 wind turbine model, as well as the use of the GE 2.3-116 at additional locations or at different hub heights. The project includes six potential turbine model layout design scenarios, which are described in detail in Appendix A.

The wind turbines being considered have the following characteristics:

- **GE 2.3-116** – A 3-blade 116-m (380 ft) rotor diameter and generating capacity of 2.3 MW. Up to 26 GE 2.3-116 turbines would be used. These turbines would have a hub height of either 80 m (262 ft), 90 m (295 ft), or 94 m (308 ft), depending on the location and layout scenario.
- **GE 2.8-127** – A 3-blade 127-m (417 ft) rotor diameter and generating capacity of 2.82 MW. Up to 67 GE 2.8-127 turbines would be used. This turbine would have a hub height of 114 m (374 ft). It is possible that 112-m (367 ft) towers would be used in a few select locations to address location-specific issues.
- **SG 2.7-129** – A 3-blade 129-m (423 ft) rotor diameter and generating capacity of 2.7 MW. Up to 67 SG 2.7-129 turbines may be used as an alternative turbine to the GE 2.8-127. This turbine would have a hub height of 109 m (358 ft).
- **V 110-2.2** – A 3-blade 110-m (361 ft) rotor diameter and generating capacity of 2.2 MW. Up to 10 V 110-2.2 turbines may be used as an alternative to the GE 2.8-127 or the SG 2.7-129. This turbine would have a hub height of 95 m (312 ft).

Although a total of 93 locations for wind turbines are included in this analysis, a maximum of only 77 turbines will ultimately be built.

The Project's associated substation and 138-kilovolt electric generation tie, which will transmit the Project's power to the point of interconnection at the Melmore Substation, is the subject of a separate filing with the Ohio Power Siting Board (OPSB) and is not reflected in this analysis.

To characterize the existing acoustic environment within the Project area, Tetra Tech, Inc. (Tetra Tech) completed a baseline sound survey. In addition, an acoustic modeling analysis was conducted to review operational sound levels resulting from the Project and compliance was assessed at nearby noise sensitive areas (i.e., occupied residences) relative to the OPSB noise requirements (see Section 2.0 of this report). The results of the baseline sound survey and modeling analysis are documented in this report.

1.1 Project Area

The Project is located within an approximately 56,900-acre portion of Seneca County (the Project Area), in northwestern Ohio, with Huron County bordering the Project Area to the east and Crawford County

bordering the Project Area to the south. The topography of Seneca County, and the Project Area, is characterized as level to gently sloping. The Project Area has moderate relief, with a high elevation of 307 m (1,007 feet) above mean sea level (amsl) in the southern portion, and a low elevation of 227 m (745 feet) amsl in the western portion. The Project Area is predominantly comprised of farmland. Areas of wooded vegetation, local roadways, and residential development also occur throughout the Project Area. Residences are widely scattered throughout the Project Area, with 2,902 residences presumed to be occupied identified within a 1-mile radius. Patches of trees and shrubs exist throughout and occur primarily between agricultural fields, in drainages, and as shelter belts around homesteads. Figure 1 presents the location of the Project wind turbines evaluated in this report, as well as the occupied residences (i.e., receptors) that were included in the modeling analysis. Ambient noise monitoring locations (MLs) and on-site meteorological stations used in the baseline sound survey are also identified on Figure 1.

1.2 Acoustic Terminology

Airborne sound is described as the rapid fluctuation or oscillation of air pressure above and below atmospheric pressure, creating a sound wave. Sound is characterized by properties of the sound waves (i.e., frequency, wavelength, period, amplitude, and velocity). Noise is defined as unwanted sound. A sound source is defined by a sound power level (L_w), which is independent of any external factors. The acoustic sound power is the rate at which acoustical energy is radiated outward and is expressed in units of watts (W). Sound energy travels in the form of a wave, a rapid fluctuation or oscillation of air pressure above and below atmospheric pressure. A sound pressure level (L_P) is a measure of this fluctuation and can be directly determined with a microphone or calculated from information about the source sound power level and the surrounding environment through predictive acoustic modeling. While the sound power of a source is strictly a function of the total amount of acoustic energy being radiated by the source, the sound pressure levels produced by a source are a function of the distance from the source and the effective radiating area or physical size of the source. In general, the magnitude of a source's sound power level is always considerably higher than the observed sound pressure level near a source because the acoustic energy is being radiated in various directions.

Sound levels are presented on a logarithmic scale to account for the large pressure response range of the human ear, and are expressed in units of decibels (dB). A dB is defined as the ratio between a measured value and a reference value usually corresponding to the lower threshold of human hearing defined as 20 micropascals (μPa). Conversely, sound power is commonly referenced to 1 picowatt (pW), which is one trillionth of a watt. Broadband sound includes sound energy summed across the frequency spectrum. In addition to broadband sound pressure levels, analysis of the various frequency components of the sound spectrum is often completed to determine tonal characteristics. The unit of frequency is Hertz (Hz), which corresponds to the rate in cycles per second that sound pressure waves are generated. Typically, a sound frequency analysis examines 11 octave (or $33\frac{1}{3}$ octave) bands ranging from 20 Hz (low) to 20,000 Hz (high). This range encompasses the entire human audible frequency range. Since the human ear does not perceive every frequency with equal loudness, spectrally varying sounds are often adjusted with a weighting filter. The A-weighted filter is applied to compensate for the frequency response of the human auditory system. Sound exposure in acoustic assessments is commonly measured and calculated as A-weighted dB (dBA).

Sound can be measured, modeled, and presented in various formats, with the most common metric being the equivalent sound level (L_{eq}). The equivalent sound level has been shown to provide both an effective and uniform method for comparing time-varying sound levels and is widely used in acoustic assessments, including in OPSB review.

Estimates of noise sources and outdoor acoustic environments, and the comparison of relative loudness are presented in Table 1. Table 2 provides additional reference information on acoustic terminology.

Table 1. Sound Pressure Levels and Relative Loudness of Typical Noise Sources and Soundscapes

Noise Source or Activity	Sound Level (dBA)	Subjective Impression	Relative Loudness (perception of different sound levels)
Jet aircraft takeoff from carrier (50 feet)	140	Threshold of pain	64 times as loud
50-hp siren (100 feet)	130		32 times as loud
Loud rock concert near stage or jet takeoff (200 feet)	120	Uncomfortably loud	16 times as loud
Float plane takeoff (100 feet)	110		8 times as loud
Jet takeoff (2,000 feet)	100	Very loud	4 times as loud
Heavy truck or motorcycle (25 feet)	90		2 times as loud
Garbage disposal, food blender (2 feet), or Pneumatic drill (50 feet)	80	Loud	Reference loudness
Vacuum cleaner (10 feet)	70		1/2 as loud
Passenger car at 65 miles per hour (mph) (25 feet)	65	Moderate	
Large store air-conditioning unit (20 feet)	60		1/4 as loud
Light auto traffic (100 feet)	50		1/8 as loud
Quiet rural residential area with no activity	45		
Bedroom or quiet living room or bird calls	40		1/16 as loud
Typical wilderness area	35	Faint	
Quiet library, soft whisper (15 feet)	30	Very quiet	1/32 as loud
Wilderness with no wind or animal activity	25		
High-quality recording studio	20	Extremely quiet	1/64 as loud
Acoustic test chamber	10	Just audible	
	0	Threshold of hearing	

Adapted from: Beranek 1988; United States Environmental Protection Agency (USEPA) 1971a.

Table 2. Acoustic Terms and Definitions

Term	Definition
Noise	Typically defined as unwanted sound. This word adds the subjective response of humans to the physical phenomenon of sound. It is commonly used when negative effects on people are known to occur.
Sound Pressure Level (L_p)	Pressure fluctuations in a medium. Sound pressure is measured in decibels referenced to 20 μPa , the approximate threshold of human perception to sound at 1,000 Hz.
Sound Power Level (L_w)	The total acoustic power of a noise source measured in decibels referenced to picowatts (one trillionth of a watt). Noise specifications are provided by equipment manufacturers as sound power as it is independent of the environment in which it is located. A sound level meter does not directly measure sound power.
A-Weighted Decibel (dBA)	Environmental sound is typically composed of acoustic energy across all frequencies. To compensate for the auditory frequency response of the human ear, an A-weighting filter is commonly used for describing environmental sound levels. Sound levels that are A-weighted are presented as dBA in this report.
Propagation and Attenuation	Propagation is the decrease in amplitude of an acoustic signal due to geometric spreading losses with increased distance from the source. Additional sound attenuation factors include air absorption, terrain effects, sound interaction with the ground, diffraction of sound around objects and topographical features, foliage, and meteorological conditions including wind velocity, temperature, humidity, and atmospheric conditions.
Octave Bands	The audible range of humans spans from 20 to 20,000 Hz and is typically divided into center frequencies ranging from 31 to 8,000 Hz for noise modeling evaluations.
Broadband Sound	Noise which covers a wide range of frequencies within the audible spectrum, i.e., 200 to 2,000 Hz.
Masking	Interference in the perception of one sound by the presence of another sound. At elevated wind speeds, leaf rustle and noise made by the wind itself can mask wind turbine sound levels, which remain relatively constant.
Frequency (Hz)	The rate of oscillation of a sound, measured in units of Hz or kilohertz (kHz). One hundred Hz is a rate of one hundred times (or cycles) per second. The frequency of a sound is the property perceived as pitch: a low-frequency sound (such as a bass note) oscillates at a relatively slow rate, and a high-frequency sound (such as a treble note) oscillates at a relatively high rate. For comparative purposes, the lowest note on a full range piano is approximately 32 Hz and middle C is 261 Hz.

Note: Compiled by Tetra Tech from multiple technical and engineering resources.

2.0 NOISE REGULATIONS AND GUIDELINES

No noise rules or regulations exist at the state level in Ohio, other than those recently established by the OPSB. The OPSB has established requirements for addressing both construction and operational noise, as well as specific guidelines for acceptable sound level increases for wind energy facilities. There are no noise requirements at the county or local levels.

The OPSB requirements include:

- A description of the noise-sensitive areas within 1 mile of the Project Area (as required in 4906-4-08(A)(3)(c)); provided in Section 1.1 of this report;
- Results of a preconstruction background noise study of the Project Area that includes measurements taken under both day and nighttime conditions (as required in 4906-4-08(A)(3)(e)); provided in Section 3.0 of this report;
- Construction noise levels at the nearest property boundary (as required in 4906-4-08(A)(3)(a)); provided in Section 5.0 of this report;
- Operational noise levels at the nearest property boundary (as required in 4906-4-08(A)(3)(b)) and at noise-sensitive areas (as required in 4906-4-08(A)(3)(c)); provided in Section 4.4 of this report, with consideration for broadband, tonal and low-frequency noise; and
- Equipment and procedures to mitigate the effects of noise emissions, as applicable, as required in 4906-4-08(A)(3)(d); provided in Section 5.0 for construction impacts and Section 4.4 for operational impacts, respectively.

The OPSB provides additional guidance within Section 4906-4-09(F) that limits the hours of general construction activities, and establishes operational noise requirements for the effect of wind turbines on non-participating landowners (in this context, a property for which the owner has not signed a waiver or otherwise agreed to be subject to a higher noise level). In addition to requiring implementation of a complaint resolution process, acceptable noise levels at non-participating properties within 1 mile are established as 5 dBA over the ambient nighttime L_{eq} , with higher daytime limits also established. For the purposes of this report, the nighttime ambient is used to assess the Project sound level. Seneca Wind's complaint resolution program is outlined in Appendix B.

3.0 EXISTING ACOUSTIC CONDITIONS

Tetra Tech conducted a baseline sound survey to characterize the existing acoustic environment near the Project. The baseline sound survey commenced on May 15, 2018 with data logged continuously over a 10-day period ending May 25, 2018.

This section summarizes the methodology used to conduct the sound survey, describes the measurement locations, and presents the measured ambient sound levels.

3.1 Field Methodology

Ambient sound level measurements were conducted using a Larson Davis Model 831 precision integrating sound-level analyzer that meets the requirements of American National Standards Institute (ANSI) Standards for Type 1 instruments. This instrument has an operating range of 5 to 140 dB and an overall frequency range of 8 to 20,000 Hz.

The Larson Davis 831 sound level analyzer is designed for service as a long-term environmental sound level data logger measuring the A-weighted sound level. Each analyzer used was enclosed in a weatherproof case and equipped with a self-contained microphone tripod. During the measurements, the microphone and windscreen were tripod-mounted at an approximate height of 1.52 to 1.82 m (5 to 6 feet) above grade. The sound level meter was calibrated at the beginning and end of the measurement period using a Larson Davis Model CAL200 acoustic calibrator following procedures that are traceable to the National Institute of Standards and Technology (NIST). Table 3 lists the measurement equipment employed during the survey. The analyzers were programmed to sample and store A-weighted and octave band sound level data, including equivalent (L_{eq}) sound levels.

Table 3. Measurement Equipment

Description	Manufacturer	Type
Signal Analyzer	Larson Davis	831
Preamplifier	Larson Davis	PRM902
Microphone	PCB	377B02
Environmental Protection Kit	Larson Davis	EPS2116
Calibrator	Larson Davis	CAL200

3.2 Monitoring Duration and Locations

The monitoring program extended over a 10-day period to collect data for a range of meteorological conditions. Monitoring locations were selected with the assistance of Seneca Wind to be representative of occupied residences located in proximity to proposed wind turbines. Continuous measurements were made in 10-minute intervals at each location and then correlated with wind speed data collected by the on-site meteorological towers shown in Figure 1. Using the sound level measurement and wind speed data, a regression analysis was conducted for each monitoring location to calculate the best fit correlation coefficient trend. The 10-minute L_{eq} sound levels were divided into daytime (7:00 a.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 a.m.) periods to show diurnal variation at each monitoring position.

A description of each of the five monitoring locations and resulting measurements (including time history and regression analysis plots) are provided below.

3.2.1 Monitoring Location 1

Monitoring Location 1 (ML-1) was situated on agricultural land at 16301-16791 Township Road 12 in Attica, Ohio (Universal Transverse Mercator [UTM] Zone 17T: 344191.2, 4547783.65). A Larson Davis 831, Serial No. 3556, was used to collect data at this location. The distance to the closest proposed wind turbine is approximately 350 m (1,148 ft) and represents the southeastern portion of the Project Area. Observations recorded during deployment indicated the location was relatively quiet, with roadway noise associated with Township Road 12, railway activities, and sporadic noise from animals onsite contributing to ambient sound levels. Figure 2 includes photographs of the monitoring location relative to one of the occupied residential structures and the viewpoint from the monitoring in the direction of the Project. Figure 3 provides the time history and Figure 4 provides the regression analyses of ambient sound levels during daytime and nighttime monitoring periods.

3.2.2 Monitoring Location 2

Monitoring Location 2 (ML-2) was situated at an occupied residence along 11119 Township Road 8 in Republic, Ohio (UTM Zone 17T: 335817, 4552881.53). A Larson Davis 831, Serial No. 3326, was used to collect data at this location. The distance to the closest proposed wind turbine is approximately 360 m (1,181 ft). Observations recorded during deployment indicated the location was relatively quiet, with agricultural activities and sporadic roadway noise potentially contributing to ambient sound levels. Figure 5 includes photographs of the monitoring location relative to one of the occupied residential structures and the viewpoint to the west from the monitoring location. Figure 6 provides the time history and Figure 7 provides the regression analyses of ambient sound levels during daytime and nighttime monitoring periods.

3.2.3 Monitoring Location 3

Monitoring Location 3 (ML-3) was situated at an occupied residence along 402 N Main Street in Attica, Ohio (UTM Zone 17T: 341527.19, 4548276.61). A Larson Davis 831, Serial No. 3545, was used to collect data at this location. The distance to the closest proposed wind turbine is approximately 620 m (2,034 ft). Observations recorded during deployment identified railway activities and sporadic roadway noise potentially contributing to ambient sound levels. Figure 8 includes photographs of the monitoring location relative to one of the occupied residential structures and the viewpoint from the monitoring in the direction of the Project. Figure 9 provides the time history and Figure 10 provides the regression analyses of ambient sound levels during daytime and nighttime monitoring periods.

3.2.4 Monitoring Location 4

Monitoring Location 4 (ML-4) was situated at an occupied residence along 7281-7497 E Country Road 12 in Bloomville, Ohio (UTM Zone 17T: 329509.08, 4546552.96). A Larson Davis 831, Serial No. 3331, was used to collect data at this location. The distance to the closest proposed wind turbine is approximately 550 m (1,804 ft). Observations during deployment were that the location was relatively quiet, with agricultural activities and sporadic roadway noise potentially contributing to ambient sound levels. Figure 11 includes photographs of the monitoring location relative to one of the occupied residential structures and the viewpoint from the monitoring in the direction of the Project. Figure 12 provides the time history and Figure 13 provides the regression analyses of ambient sound levels during daytime and nighttime monitoring periods.

3.2.5 Monitoring Location 5

Monitoring Location 5 (ML-5) was situated at an occupied residence along 4400 E Country Road 12 in Bloomville, Ohio (UTM Zone 17T: 324716.52, 4543934.7). A Larson Davis 831, Serial No. 3219, was used to collect data at this location. The distance to the closest proposed wind turbine is approximately 282 m (925 ft). Observations recorded during deployment indicated the location was relatively quiet, with

agricultural activities and sporadic roadway noise potentially contributing to ambient sound levels. Figure 14 includes photographs of the monitoring location relative to one of the occupied residential structures and the viewpoint from the monitoring in the direction of the Project. Figure 15 provides the time history and Figure 16 provides the regression analyses of ambient sound levels during daytime and nighttime monitoring periods.

3.3 Baseline Sound Survey Results

Table 4 provides the results of the regression analyses for each monitoring location and cumulatively for all locations, representing the ambient sound levels across the Project Area. Table 4 displays daytime and nighttime ambient sound levels for each monitoring location within the Project Area for wind speed conditions ranging from calm to maximum rotational wind speed. The results show a generally homogenous ambient acoustic environment throughout the Project Area with limited variation in measured sound levels.

Table 4. Baseline Sound Survey Results, L_{eq} (dBA)

4.0 ACOUSTIC MODELING METHODOLOGY

Sound generated by an operating wind turbine is made up of both aerodynamic and mechanical sound, with the dominant sound component from modern utility scale wind turbines being largely aerodynamic. Aerodynamic sound refers to the sound produced from air flow and the interaction with the wind turbine tower structure and moving rotor blades. Mechanical sound is generated at the gearbox, generator, and cooling fan, and is radiated from the surfaces of the nacelle and machinery enclosure and by openings in the nacelle casing. Due to the improved design of wind turbine mechanical components and the use of improved noise damping materials within the nacelle, including elastomeric elements supporting the generator and gearbox, mechanical noise emissions have been minimized in modern wind turbines. Sound reduction elements designed as a part of the wind turbines include impact noise insulation of the gearbox and generator, sound-reduced gearbox, sound-reduced nacelle, and rotor blades designed to minimize noise generation.

Wind energy facilities are somewhat unique in that the sound generated by each individual wind turbine will increase as the wind speed increases up to a certain point. Wind turbine sound is negligible when the rotor is at rest, increases as the rotor tip speed increases, and is generally constant once rated power output and maximum rotational speed are achieved. The wind turbine maximum sound power level will be reached at approximately 10 m/s (22.4 mph) at the hub height according to the GE specifications for the proposed equipment. It is important to recognize that, as wind speeds increase, background ambient sound levels will generally increase as well, resulting in acoustic masking effects. The net result is that, during periods of elevated wind speeds when higher wind turbine sound emissions occur, the sound produced from a wind turbine operating at maximum rotational speed may be largely or fully masked due to wind-generated sound in foliage or vegetation. In practical terms, this means a nearby receptor would tend to hear leaves or vegetation rustling rather than wind turbine noise. This relationship is expected to further minimize the potential for adverse noise effects of the Project, but is not taken into account in the modeling results.

4.1 Acoustic Modeling Software and Calculation Methods

The operational acoustic assessment was performed using the Project shown in Figure 1, consisting of 93 potential wind turbine locations with two scenarios evaluating different turbine types; wind turbines will only be constructed in 77 of the studied locations. The acoustic modeling analysis was conducted using the most recent version of DataKustic GmbH's computer-aided noise abatement program or CadnaA (v 2017 MR1). CadnaA is a comprehensive 3-dimensional acoustic software model that conforms to the International Organization for Standardization (ISO) standard ISO 9613-2 "Attenuation of Sound during Propagation Outdoors." The engineering methods specified in this standard consist of full (1/1) octave band algorithms that incorporate: geometric spreading due to wave divergence; reflection from surfaces; atmospheric absorption; screening by topography and obstacles; ground effects; source directivity; heights of both sources and receptors; seasonal foliage effects; and meteorological conditions.

Topographical information was imported into the acoustic model using the official United States Geological Survey (USGS) digital elevation dataset to accurately represent terrain in three dimensions. Terrain conditions, vegetation type, ground cover, and the density and height of foliage can also influence the absorption that takes place when sound waves travel over land. The ISO 9613-2 standard accounts for ground absorption rates by assigning a numerical coefficient of G=0 for acoustically hard, reflective surfaces and G=1 for absorptive surfaces and soft ground. If the ground is hard-packed dirt, typically found in industrial complexes, pavement, bare rock or for sound traveling over water, the absorption coefficient is defined as G=0 to account for reduced sound attenuation and higher reflectivity. In contrast, ground covered in vegetation, including suburban lawns, livestock and agricultural fields (both fallow with bare soil and planted with crops), will be acoustically absorptive and aid in sound attenuation (i.e., G=1.0). A mixed (semi-reflective) ground factor of G=0.5 was used in the Project acoustic modeling analysis. In

addition to geometrical divergence, attenuation factors include topographical features, terrain coverage, and/or other natural or anthropogenic obstacles that can affect sound attenuation and result in acoustical screening. To be conservative, sound attenuation through foliage and diffraction around and over existing anthropogenic structures, such as buildings, was ignored in this analysis.

Sound attenuation by the atmosphere is not strongly dependent on temperature and humidity; a temperature of 10° Celsius (50° Fahrenheit) and 70 percent relative humidity parameters were selected as representative of a median. Atmospheric absorption depends on temperature and humidity, and is most important at higher frequencies. Over short distances, the effects of atmospheric absorption are minimal. The ISO 9613-2 standard calculates attenuation for meteorological conditions favorable to propagation, i.e., downwind sound propagation, or what might occur typically during a moderate atmospheric ground level inversion. Though a physical impracticality, the ISO 9613-2 standard simulates omnidirectional downwind propagation. For receivers located between discrete wind turbine locations or wind turbine groupings, the acoustic model may, therefore, result in over-prediction. In addition, the acoustic modeling algorithms essentially assume laminar atmospheric conditions, in which neighboring layers of air do not mix. This is also a conservative assumption, as air movement naturally incorporates turbulent eddies and micrometeorological inhomogeneities when winds change speed or direction, which would interfere with the sound wave propagation path and increase attenuation effects to reduce experienced sound levels.

4.2 Acoustic Modeling Input Parameters

Wind turbine manufacturers report wind turbine sound power data at integer wind speeds referenced to the effective hub height, ranging from cut-in to full-rated power per International Electrotechnical Commission (IEC) standard IEC 61400-11:2006 Wind Turbine Generator Systems – Part 11: Acoustic Noise Measurement Techniques. This IEC standard was developed to ensure consistent and comparable sound emission data of utility-scale wind turbines between manufacturers. Tables 5 and 6, respectively, present a summary of sound power data correlated to winds at the hub heights of 80 m (262 ft), 90 m (295 ft), and 94 m (308 ft) for the GE 2.3-116 as well as at the hub height of 114 m (374 ft) for the GE 2.8-127 wind turbines. Table 7 present a summary of sound power data correlated to winds at the hub height of 109 m (358 ft) for the SG 2.7-129 wind turbines. Table 8 present a summary of sound power data correlated to winds at the hub height of 95 m (312 ft) for the V110-2.2 wind turbines.

The specification for the wind turbines includes an expected warranty confidence interval, or k-factor, of 2 dB, which was added to the nominal sound power level in the acoustic model. This confidence interval applies a margin to reflect the applied probability level and standard deviation for test measurement reproducibility, as well as product variability.

Table 5. Broadband Sound Power Levels (dBA) Correlated with Wind Speed, GE 2.3-116

Wind turbines can be somewhat directional, radiating more sound in some directions than others. The IEC test measurement protocol requires that sound measurements are made for the maximum downwind directional location when reporting apparent sound power levels. Thus, it is assumed that wind turbine directivity and sound-generating efficiencies are inherently incorporated in the sound source data and used in acoustic model development. A summary of sound power data by octave band center frequency for wind turbines operating at maximum rotation are presented in Tables 9, 10, 11 and 12 (1/1 octave band frequency data provided with stated intended use limited for informational purposes only).

Table 9. Sound Power Level by Octave Band Center Frequency, GE 2.3-116

4.3 Critical Design Wind Speed

The critical design wind speed is defined as the operational condition when the greatest differential occurs between the pre-construction background sound level and the wind turbine sound power level at the corresponding given wind speed. Although not initially intuitive, the operational noise condition that results in the greatest incremental increase relative to baseline does not always occur at full-rated power, when the wind turbine is at its maximum noise emission level. Table 11 identifies the critical design wind speed for the GE 2.8-127-60 Hz (which is not only the primary turbine type used for scenario 1, 3, and 5, but as reflected in Tables 5 and 6, has the higher noise emission level of the GE units) assuming a wind speed at the maximum hub height for the Project (114 m (374 ft)); critical design wind speed is identified by comparing the net differential between the wind turbine sound power level and the background nighttime L_{eq} sound level measured during the 2018 survey and at the average hub height. Table 1 shows that, for the GE 2.8-127-60 Hz, the critical design wind speed occurs at the reference wind speed range of 9 m/s (20.1 mph).

Acoustic modeling was completed for scenarios 1, 3, and 5 at the critical design wind speed, where the sound power octave band data was scaled accordingly. The results from modeling these scenarios were then used to evaluate the Project's sound level and compare it to nighttime ambient conditions; at 9 m/s (20.1 mph), nighttime ambient was measured to be 46 dBA.

Table 13. Critical Design Operational Condition, GE 2.8-127

Wind Speed	4 m/s	5 m/s	6 m/s	7 m/s	8 m/s	9 m/s	10 m/s	11 m/s	12 m/s
GE 2.8 L_{max}

Bold type indicates critical design wind speeds.

Scenario 5 incorporates the V 110-2.2 wind turbine model. Table 14 identifies the critical design wind speed for the V 110-2.2 assuming a wind speed at the maximum hub height for the Project (114 m (374 ft)); critical design wind speed is identified by comparing the net differential between the wind turbine sound power level and the background nighttime L_{eq} sound level measured during the 2018 survey and at the average hub height. Table 14 shows that, for the V 110-2.2, the critical design wind speed occurs at the reference wind speed range of 8 m/s (17.9 mph).

Additional acoustic modeling was completed for scenario 5 at the critical design wind speed, where the sound power octave band data was scaled accordingly. The results from modeling this scenario were then used to evaluate the Project's sound level and compare it to nighttime ambient conditions; at 8 m/s (17.9 mph), nighttime ambient was measured to be 44 dBA.

Table 14. Critical Design Operational Condition, V 110-2.2

Wind Speed	4 m/s	5 m/s	6 m/s	7 m/s	8 m/s	9 m/s	10 m/s	11 m/s	12 m/s

Bold type indicates critical design wind speeds.

Table 15 identifies the critical design wind speed for the SG 2.7-129 assuming a wind speed at the maximum hub height for the Project (114 m (374 ft)); critical design wind speed is identified by comparing the net differential between the wind turbine sound power level and the background nighttime L_{eq} sound level measured during the 2018 survey and at the average hub height. Table 15 shows that, for the SG 2.7-129, the critical design wind speed occurs at the reference wind speed range of 8 m/s (17.9 mph).

Acoustic modeling was completed for scenario 2, 4, and 6 at the critical design wind speed, where the sound power octave band data was scaled accordingly. The results from modeling this scenario were then used to evaluate the Project's sound level and compare it to nighttime ambient conditions; at 8 m/s (17.9 mph), nighttime ambient was measured to be 44 dBA.

Table 15. Critical Design Operational Condition, SG 2.7-129

Bold type indicates critical design wind speeds.

4.4 Acoustic Modeling Results and Compliance

Acoustic modeling was completed for wind turbine critical design wind speed of 9 m/s (20.1 mph) scenarios 1, 3, and 5 and 8 m/s (17.9 mph) for scenarios 2, 4, 5, and 6. When calculating received sound levels, it was assumed that all wind turbines were operating continuously and concurrently at the given

operating condition. When compared to the measured nighttime ambient sound level, the acoustic modeling results for the identified scenarios indicate that initial modeling results exceed an increase of 5 dBA over ambient for some non-participating landowners under some scenarios.

For scenario 1, Seneca Wind has incorporated additional noise reduction features at 12 turbine locations to reduce sound levels at non-participating residences. Scenarios 3 and 5 incorporated additional noise reduction features at 11 turbine locations. The noise emission level for the GE 2.8 in noise-reduced mode is summarized in Table 16. With the incorporation of the additional noise reduction, the noise level at all non-participating residences will be 51 dBA or below for scenarios 1, 3, and 5 (9 m/s (20.1 mph)) and will be 49 dBA or below for scenario 5 (8 m/s (17.9 mph)). Therefore, the Project noise levels for scenarios 1, 3, and 5 will comply with the OPSB noise criterion.

Table 16. Sound Power Level by Octave Band Center Frequency, GE 2.8-127 with Noise Reduction

Frequency (Hz)	Octave Band Sound Power Level (dBA)								Broadband (dBA)	
	32	63	125	250	500	1000	2000	4000		
GE 2.8 -127 with Noise Reduction	82.8	92.6	97.2	98.2	100.4	103.8	102.7	95.0	76.9	108.5

For scenarios 2, 4, and 6, Seneca Wind has incorporated additional noise reduction features at two turbine locations to reduce sound levels at non-participating residences. The noise emission level for the SG 2.7-129 in noise-reduced mode is summarized in Table 17. With the incorporation of the additional noise reduction, the noise impacts at all non-participating residences will be 49 dBA or below and will, therefore, comply with the OPSB noise criterion.

Table 17. Sound Power Level by Octave Band Center Frequency, SG 2.7-129 with Noise Reduction

Frequency (Hz)	Octave Band Sound Power Level (dBA)								Broadband (dBA)	
	32	63	125	250	500	1000	2000	4000		
SG 2.7 -129 with Noise Reduction	70.9	84.1	91	96	99	100.9	100.0	95.6	86.5	106.0

The revised acoustic modeling results by residence, incorporating the identified wind turbines operating in noise reduced mode, are included in the results presented in Appendix C.

A sound contour plot displaying Project operational sound levels in color-coded isopleths for each scenario is provided in Figures 17 through 23. These figures show broadband (dBA) operational sound levels at wind speeds corresponding to wind turbine operation at the critical design wind speed. The detailed modeling results with the incorporation of the noise-reduced turbines are presented in Appendix C; Table C-1 includes the residence identifier, UTM coordinates, residence status (participant or non-participant), and the received sound levels for all scenarios at each residence. The **bold** sound levels in Table C-1 indicate exceedances greater than 5 dBA over the ambient sound level. The tabulated results and contour plot are independent of the existing acoustic environment and are representative of expected Project sound levels only.

5.0 CONSTRUCTION NOISE

Acoustic emission levels for activities associated with Project construction were based upon typical ranges of energy equivalent noise levels at construction sites, as documented by the USEPA (USEPA 1971b) and the USEPA's "Construction Noise Control Technology Initiatives" (USEPA 1980). The USEPA methodology distinguishes between type of construction and construction phase.

Using those energy equivalent noise levels (L_{eq}) as input to a basic propagation model, construction noise levels were calculated at the nearest non-participating residential structure and at the furthest non-participating residential structure.

The basic model assumed spherical wave divergence from a point source located at the acoustic center of a turbine location. Furthermore, the model conservatively assumed that all pieces of construction equipment associated with an activity would operate simultaneously for the duration of that activity. An additional level of conservatism was built into the construction noise model by excluding potential shielding effects due to intervening structures and buildings along the propagation path from the site to receiver locations.

Construction activities associated with the Project also have the potential for localized noise on a temporary basis as construction activities progress through certain locations within the Project Area. Construction activities the Project can be generally divided into four phases:

1. *Site Clearing*: The initial site mobilization phase includes the establishment of temporary site offices, workshops, stores, and other on-site facilities. Installation of erosion and sedimentation control measures will be completed as well as the preparation of initial haulage routes.
2. *Excavation*: This phase would begin with the excavation and formation of access roads and preparation of laydown areas. Excavation for the concrete turbine foundations would also be completed, which incorporates necessary rock drilling.
3. *Foundation Work*: Construction of the reinforced concrete turbine foundations would take place in addition to installation of the internal transmission network.
4. *Wind Turbine Installation*: Delivery of the turbine components would occur, followed by their installation and commissioning.

Note that these activities would occur sequentially for discrete groupings of wind turbines, with the potential for overlap. In addition to the wind turbines, construction activities will also occur for supporting infrastructure. The electrical collector lines are likely to be completed while each respective wind turbine is being constructed; other Project-related elements, such as the operations and maintenance building, would be constructed independently.

The construction of the Project is likely to cause short-term but unavoidable noise impacts. Based on sound propagation calculations, construction sound levels are predicted to range from 55 dBA to 62 dBA at the nearest non-participating residential structure (approximately 384 m (1,260 ft) from the turbine). Table 18 summarizes the predicted Project construction noise levels at varying distances; sound decreases with distance. Periodically, sound levels may be higher or lower than those presented in Table 18 depending on several factors, such as the type, number, and age of construction equipment in use, the specific equipment manufacturer and model, the operations being performed, and the overall condition of the equipment and its exhaust system mufflers.

Table 18. Projected Construction Noise Levels by Phase (dBA)

Construction Phase	Construction Noise Level at 50 Feet	Construction Noise Level at 1,260 Feet (nearest non-participating residential structure)	Construction Noise Level at 1,500 Feet
Phase 1: Site Clearing	86	58	56
Phase 2: Excavation	90	62	61
Phase 3: Foundation Work	85	57	55
Phase 4: Wind Turbine Installation	83	55	54

All reasonable efforts will be made to minimize the temporary impact of construction noise. As the design of the Project progresses and construction scheduling is finalized, community notifications with information regarding the construction schedule and duration will be provided. To the extent practicable, louder construction activities (rock drilling and horizontal directional drilling) will be scheduled during daytime hours, between 10:00 a.m. and 5:00 p.m., and general construction activities will be limited to the greatest extent practicable to the hours of 7:00 a.m. to 7:00 p.m., consistent with OPSB Section 4906-4-09(F)(1). Where necessary for such activities requiring continuous activity (such as foundation pours) or for activities where daytime activities might be more disruptive (such as flying rotors), care will be taken to minimize noise to the greatest extent practicable. Internal combustion engines will be equipped with appropriately-sized muffler systems to minimize noise emissions. Blasting is not expected to be required based on preliminary geological studies conducted for the Project; appropriate notifications will be made should it be required.

In addition to construction equipment, the increased levels of traffic on local roads, associated with workers and deliveries, can also result in temporary increases in sound levels. However, travel will occur largely along existing roads that currently experience truck traffic or on accessways across private property. At the early stage of construction, equipment and materials will be delivered, and set-up will occur at laydown yards. Site preparation efforts (e.g., creation of access roads, preparation of foundation platforms) will require that equipment such as hydraulic excavators and associated spreading and compacting equipment be delivered and used at each location, moving on to the next location once each task is completed. Equipment for lifting the towers and vehicles delivering turbine components is larger and will move more slowly on the local roadways. Deliveries will occur for each wind turbine and will be timed, to the extent practicable, to allow for immediate assembly. The local community will be notified of the timing of large equipment deliveries. For the cranes and assembly equipment, once they are local, they will move from location to location until all wind turbines are installed. Traffic noise is not expected to contribute significantly to community sound, particularly due to its transient nature.

6.0 CONCLUSIONS

Project operational sound has been calculated for all six scenarios, and has been determined to meet OPSB standards, even with the conservative assumptions and maximum impact case reflected in the modeling. For most locations, standard mitigation design can achieve this goal. However, for 12 wind turbines for the scenario 1; 11 wind turbines for scenario 3 and 5; and 2 wind turbines for scenarios 2, 4, and 6, where they have the potential to affect non-participating landowners at slightly higher levels, additional mitigation has been incorporated to achieve the OPSB standard.

Appendix B

Complaint Resolution Procedure

Seneca Wind Complaint Resolution Program

1. INTRODUCTION

Seneca Wind LLC (Seneca Wind) has developed a complaint resolution program for implementation during the construction of the Seneca Wind project (the Project) to provide an effective process for identification and resolution of concerns voiced by members of the community.

Seneca Wind is committed to complying with requirements established through the Ohio Power Siting Board (OPSB) and other regulatory processes, and to establishing an accessible process for community members to voice concerns and for those concerns to be addressed as quickly and effectively as possible. Maintaining detailed records of all complaints and resulting actions is an important aspect of the complaint resolution program.

Seneca Wind's policy is to take all reasonable necessary actions to rectify legitimate interference or disturbances that are a direct result of the Project.

2. COMPLAINT RESOLUTION PROCEDURE

2.1 Seneca Wind Contacts

Seneca Wind will establish a toll-free telephone number prior to the Project being commercially operational and will provide that number to the county commissioners, township trustees, emergency responders, schools, and public libraries within the Project Area; that number will also be posted on the Project website. To register a complaint, individuals may either call the telephone number and leave a message or go to the local construction office during regular business hours.

2.2 Notification

In addition to providing the contact information and procedure to the officials and public locations noted above, Seneca Wind will maintain a Project contact list for residents and will provide notification to residences located within 1 mile of construction activities that construction is about to commence.

2.3 Complaint Documentation and Follow-Up

Seneca Wind will keep a logbook to register every complaint received. The logbook will include pertinent information about the person making the complaint, the issues surrounding the complaint, and the date the complaint was received; an example of a complaint resolution form is attached.

The logbook will also document Seneca Wind's recommended resolution, the date agreement was reached on a proposed resolution, and the date when the proposed resolution was implemented. Seneca Wind personnel will generate a quarterly report based on the information recorded in the log book about the nature and resolution of all complaints received in that quarter, and file the report with the OPSB on January 31, April 30, July 31, and October 31 of each calendar year or portion thereof during construction.

Individuals who register a complaint with Seneca Wind will receive correspondence from Seneca Wind no later than 2 business days after registering the complaint. The intent of the initial correspondence is to gather more information to better understand the complaint. Within 30 days of the complaint being logged, Seneca Wind will initiate reasonable action to resolve the legitimate interference or disturbance that is a direct result of the Project.

If Seneca Wind and the complaining individual cannot agree to a resolution, Seneca Wind will provide a summary of the complaint and proposed resolution to the complaining individual so the complaint can be brought to the OPSB.

**Seneca Wind
Complaint Resolution Form**

Complaint Log Number: _____
Complainant's name and address:
Phone number/email:
Date complaint received: _____
Time complaint received: _____
Date complainant first contacted: _____
Nature of complaint:
Definition of problem after investigation:
Description of corrective measures taken:
Complainant's signature: _____ Date: _____
This information is certified to be correct:
Site Manager's Signature: _____ Date: _____

(Attach additional pages and supporting documentation, as required.)

Appendix C

Tabulated Acoustic Modeling Results by Residence
