I. Project Overview

Fisher Associates, P.E., L.S., L.A., D.P.C (FA) has been contracted by Hecate Energy Highland 4 LLC (Hecate Energy) to complete a Transportation Study for the proposed New Market Solar I, 65 MW solar project. This study has been prepared to satisfy the relevant portions of the Ohio Power Siting Board (OPSB) requirements specified in the Ohio Administrative Code, Sections 4906-4-06(F)(3) and 4906-4-06(F)(4).

Section 4906-4-06(F)(3) states: "The applicant shall evaluate and describe the anticipated impact to roads and bridges associated with construction vehicles and equipment delivery. Describe measures that will be taken to improve inadequate roads and repair roads and bridges to at least the condition present prior to the project."

Section 4906-4-06(F)(4) states: "The applicant shall list all transportation permits required for construction and operation of the project, and describe any necessary coordination with appropriate authorities for temporary or permanent road closures, lane closures, road access restrictions, and traffic control necessary for construction and operation of the proposed facility."

The proposed New Market Solar I project is located in Clay and White Oak Townships, Highland County, Ohio as depicted on the location map in Appendix A, Exhibit 1. However the project haul routes utilizes additional roads in Hamer Township. The proposed project, including the distribution line, layout is shown on the exhibits provided in Appendix A.

A. Transportation Access Points

All construction equipment, aggregate, supplies, and general construction traffic should approach the project area from the north off State Route 138. Unless authorized by the developer, this traffic will use the existing state routes until it reaches the project's designated public roads. The two possible routes off of State Route 138, are New Market road (CH 5) heading east and Hollowtown road (CH 24) heading south.

The jurisdictions of the project's designated public roads proposed to be used as shown in Appendix B are:

 Highland County – New Market Road (CH 5), Hollowtown Road (CH 24), Gath Road (CH 2), Stringtown Road (CH 60) & Edwards Road (CH 56)

Based on the proposed project, it is estimated that there will be a minimum of nine (9) individual site access points to the solar panels. The project will utilize one access off Edwards Road (CH 56), two (2) access locations off Hollowtown (CH 24) Road and six (6) access locations off New Market Road (CH 5). The project is otherwise landlocked from adjacent public roadways.

II. Pre-Construction Roadway Characteristics

A. Traffic Volumes and Accident Data

Existing data on vehicle traffic volumes and accidents within the study area was obtained from the ODOT Transportation Information Mapping System (TIMS) and can be found in Appendix C. The Annual Average Daily Traffic (AADT) is listed for the State and county roads, but the local town roads had limited traffic volume data. Detailed capacity analysis was not completed for this study, however, field observation of the transportation network did not reveal any locations where traffic flow and/or capacity appeared to create undue delay for the traveling public.

The table below summarizes the traffic conditions on the roads within the study area.

Roadwa	y Name	Total Road Widths	AADT
County Highway 5	New Market Road	18' - 21'	558
County Highway 24	Hollowtown Road	16' – 17'	NA
County Highway 2	Gath Road	19' – 20'	220
County Highway 56	Edwards Road	18' – 20'	NA
County Highway 60	Stringtown Road	19'	NA

^{*} AADT = Average Annual Daily Traffic

According to TIMS, between 2017 and 2019, there were three (3) accidents within the transportation study area. Of the three accidents, two were at intersections; one at the intersection of State Route 138 and New Market Road and one at the intersection of New Market Road and Hollowtown Road. The other accident occurred on New Market Road between Euverard Road and Hollowtown Road. State Route 138 has a posted speed limit of 45 mph and, therefore, extra caution must be taken while turning onto and off of that highway. Of the three total accidents, none were fatal. Therefore, the fatal accident rate (fatal accidents/million vehicle miles) is zero (0) compared to the 2018 Ohio statewide average fatal accident rate of 0.93 fatal accidents/100 million vehicle miles, as found on the United State Department of Transportation's National Highway Traffic Safety Administration's website.

B. School Bus Route Information and Mass Transit Systems

The students in the project area attend the Lynchburg-Clay School District in Lynchburg. The high school and elementary school are located on the same campus, which is located about 10.4 miles north of the project site at 6762 & 6760 State Route 134 (SR 134) respectively. The middle school is about 12.8 miles north of the project site at 8250 State Route 134 (SR 134). Due to the distance from the schools and lack of sidewalks, most of the students are picked-up/dropped-off at their place of residence. The number of stops and buses within the project area is limited due to the low density of houses within and adjacent to the

^{**} Traffic volumes obtained from ODOT Transportation Information Mapping System (TIMS) on 02/03/2020. Traffic volumes for Hollowtown Road, Edwards Road, & Stringtown Road were unavailable.

project area. Because the majority of the project activities and deliveries will likely occur during the middle of the day, the impacts to the local school bus routes should be minimal.

There are no public rail or bus mass transit systems in the project area.

C. Emergency Service Responder Information

Highland County is served by Mercy Health – Mount Orab Medical Center and Mercy Health – Clermont Hospital. These emergency services are located approximately 15 miles southwest of the project site. They can be reached by travelling southwest on Route 138, south on Route 86 and west on Route 32.

An Emergency Response Plan for the project will be implemented which will include procedures (preconstruction through project operation) for fire and emergency services. This plan will outline on-site equipment and the procedures for fire suppression, medical and weather emergency evacuation as well as other critical areas. In addition, regularly scheduled meetings will be held with local emergency providers. As with any large-scale development, project components will meet all state and federal safety and fire codes.

D. Traffic Routes Load Bearing and Structural Rating Information

A field review of existing conditions along the roads within the project area was conducted by Fisher Associates on January 27, 2020. Data observed during the site visit as depicted in Appendices A and D, includes:

- Bridge and road load postings
- Road widths, type, and pavement condition
- Culvert cover and conditions
- Posted signs of caution

Bridge and Road Load Posting Restrictions

There are no posted loading restrictions to the bridges located on the transport route. As shown in Appendix A, the ODOT bridges along the transportation public roads all are rated as good condition:

ODOT Bridge Number	Roadway	Name	Feature Intersected	Sufficiency Rating	National Bridge Inventory Rating
3634345	County Highway 2	Gath Road	Flat Run Creek	99.9	Good

Road Surface Type and Widths

As depicted on the Road Width and Conditions Exhibit (Appendix A, Exhibit 2), the road surface types along the transport route are all asphalt. The table below summarizes the road conditions along the transport route.

Roadway	Name	Total Road Widths	Road Condition
County Highway 5	New Market Road	18' - 21'	Road Patch Depressed
County Highway 24	Hollowtown Road	16' – 17'	Shallow Culvert Cover
County Highway 2	Gath Road	19' – 20'	No apparent deficiencies
County Highway 56	Edwards Road	18' – 20'	No apparent deficiencies
County Highway 60	Stringtown Road	19'	No apparent deficiencies

The roads that are less than 18' in overall width may require a construction traffic plan so as to not negatively impact the landowners/residents and limit trucks driving off the pavement. There are some pavement repair locations and depressions which are depicted on the Areas of Concern Exhibit (Appendix A, Exhibit 3) and corresponding photographs in Appendix D. The least stable pavement section of the study area, which should be monitored during hauling and peak construction activities, was a patched section over a 24" culvert pipe on New Market road. See Area of Concern 1, in Appendix D The remainder of the transport roads do not appear to exhibit any underlying issues, but rather normal aging that requires routine maintenance. Hecate Energy will consult with the County Engineer regarding any necessary pre-construction work. However at the time of the study, there does not appear to be any significant structural concerns to the existing roads from a transportation perspective.

Culvert Cover and Conditions

During the site visit, it was observed that there are culverts of varying sizes that have recently been replaced and appear to be in good structural condition. Some have minimal cover; however, these are either small or are made of concrete in order to handle the vehicle and equipment loads. Two larger culverts, both located along Hollowtown Road, have shallow cover and may need repair work done during/after construction. Each pipe should be analyzed to determine if necessary improvements are needed to accommodate the construction traffic. As noted on the Areas of Concern Exhibit (Appendix A, Exhibit 3) and corresponding photographs in Appendix D, some asphalt patches at these new culvert locations are deteriorating faster than the remaining road surface or there is some settlement on either end of the culvert. In these cases, the additional traffic may increase the rate of degradation and will need to be monitored during construction for possible upgrades.

- New Market Road: concrete patch depressed over 24 inch (Area of Concern 1).
- Hollowtown Road: shallow cover over 72 inch concrete elliptical pipe (Area of Concern 3).
- Hollowtown Road: shallow cover over 36 inch concrete culvert (Area of Concern 4).

Hecate Energy will consult with the County Engineer regarding any necessary preconstruction work.

Posted Signs of Caution

As depicted on the Areas of Concern Exhibit (Appendix A, Exhibit 3) and corresponding photographs in Appendix D, there is one area that has been posted for flood water potential, on Gath Road (CH 2) just outside the study limits. During and after heavy storm events, construction vehicles traveling along Gath Road should use caution and be aware of standing water along or adjacent to the cartway.

Overhead Clearance

Because the construction vehicles for the project will be legal heights and no intersection improvements are proposed, there will not be any issues with vehicle clearance to overhead electric crossings and potential vegetation or tree branch overhang concerns.

III. Trip Generation Characteristics

A. Vehicle Trips Frequency

A truck load estimate calculation during the construction phase is included in Appendix E. Any assumptions in the calculations are based on anticipated solar project loads. Based on the site visit, potential locations for proposed access roads off of the transport roads are depicted on the exhibits in Appendix A. As the construction traffic volumes do not appear to exceed capacities, the roadways should not be significantly impacted by standard construction traffic.

During operation and maintenance, the facility will not generate a significant volume of traffic, with the anticipation of only a few pickup trucks during routine scheduled maintenance as well as unanticipated unscheduled maintenance periods.

IV. Traffic and Transportation Impacts of the Facility

A. Projected Future Traffic Conditions

While construction vehicles are traveling along project area and delivery route roadways, the existing traffic may experience minor delays to allow for the safe passage of these vehicles.

During development of the potential road use agreements if necessary, the Applicant will coordinate with appropriate authorities to determine applicable thresholds and procedures for implementing temporary or permanent road closures, lane closures, road access restrictions, and traffic control.

During operation and maintenance, the facility will not generate a significant volume of traffic. Therefore, any projected additional future traffic will be negligible.

B. Adequacy of the Road System to Accommodate Projected Traffic

Truck load assumptions are based on typical solar projects that will need to be finalized in conjunction with the anticipated county road use agreements, if required. Roads with low strength and/or poor surface conditions may require improvement after construction traffic. All the transport roads do not appear to exhibit an underlying issue, but just normal aging that requires routine maintenance. During the pre-construction period, the applicant will coordinate with the county and townships to determine if any pre-construction road maintenance will be needed, but significant structural improvements are not anticipated. However, due to the width of some of the roads (less than 16' wide), limited construction traffic management plans may need to be created to avoid negatively impacting the residents/local traffic.

To calculate the number of trucks in Appendix E, we assumed WB-50's (8.5 ft wide x 42.5 ft long x 10 ft high) for the solar panel delivery and standard dump trucks for gravel & asphalt delivery. An estimation of 3.800-4,200 trucks will be needed for the project, but none of the vehicles will be oversized or overweight. Roads will need to be monitored prior to, and during construction and reviewed afterwards to determine the required repairs, if any. Roads will be returned to pre-construction conditions.

During operation and maintenance, the facility will not generate a significant volume of traffic. Therefore improvements and continuous monitoring to the road system are not necessary to accommodate projected operations traffic.

C. Traffic and Transportation Mitigation Measures

In conjunction with the anticipated county road use, mitigation measures to address maintenance will be developed as the project's layout is finalized. Final engineering design will be required prior to construction activities to ensure all transportation related impacts have been addressed to the satisfaction of the local county highway department. High traffic

areas include all of New Market road which serves as the primary thoroughfare through the project site.

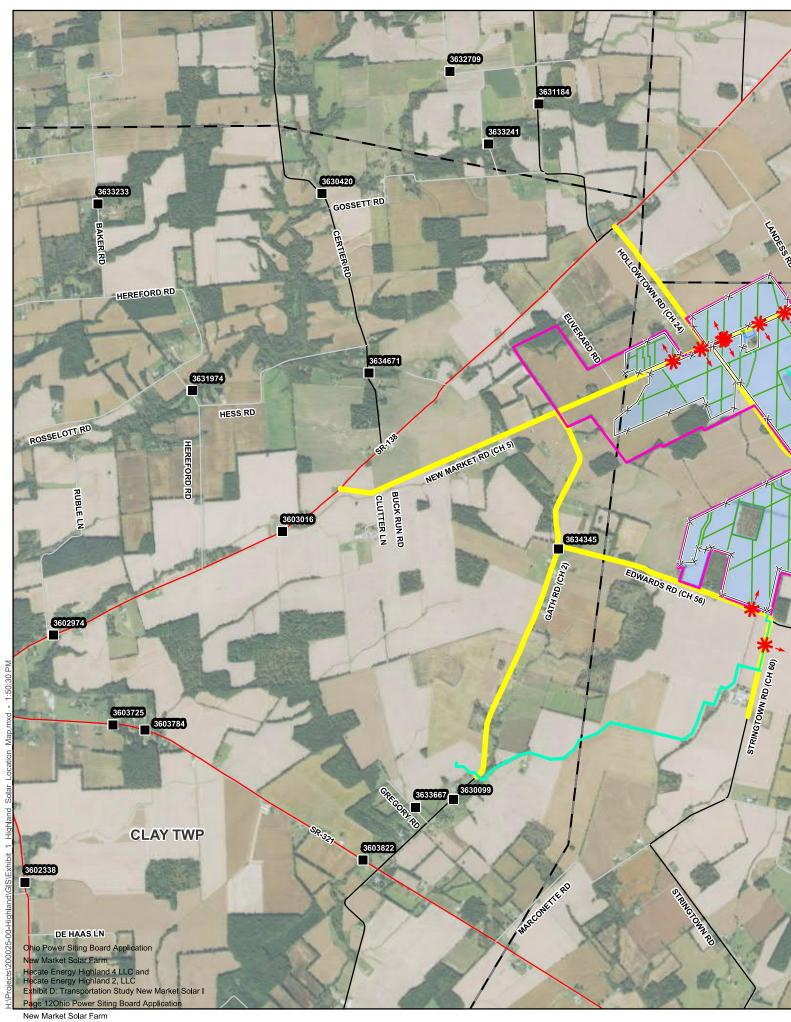

All roads should be monitored during construction for potholing and deterioration of the pavement to ensure they are safe for general construction and local roadway traffic. The volume and weight of both the general construction traffic may cause some distress that could require temporary repair. These temporary repairs/improvements could include repaving with asphalt, temporary traffic signs, etc. and be as a condition of a road use agreement with the county or township. After completion of construction activities, there may be some improvements needed due to any damage caused by the high frequency of vehicle traffic (especially on any roads that had temporary repairs made during the construction activities). Repairing the roadways to pre-construction conditions may include using treatments such as oil and stone or hot or cold mix asphalt, which may be required should a road use agreement be required. Other repairs will likely require some asphalt patching or possibly some asphalt removal, subgrade compaction, and asphalt patching.

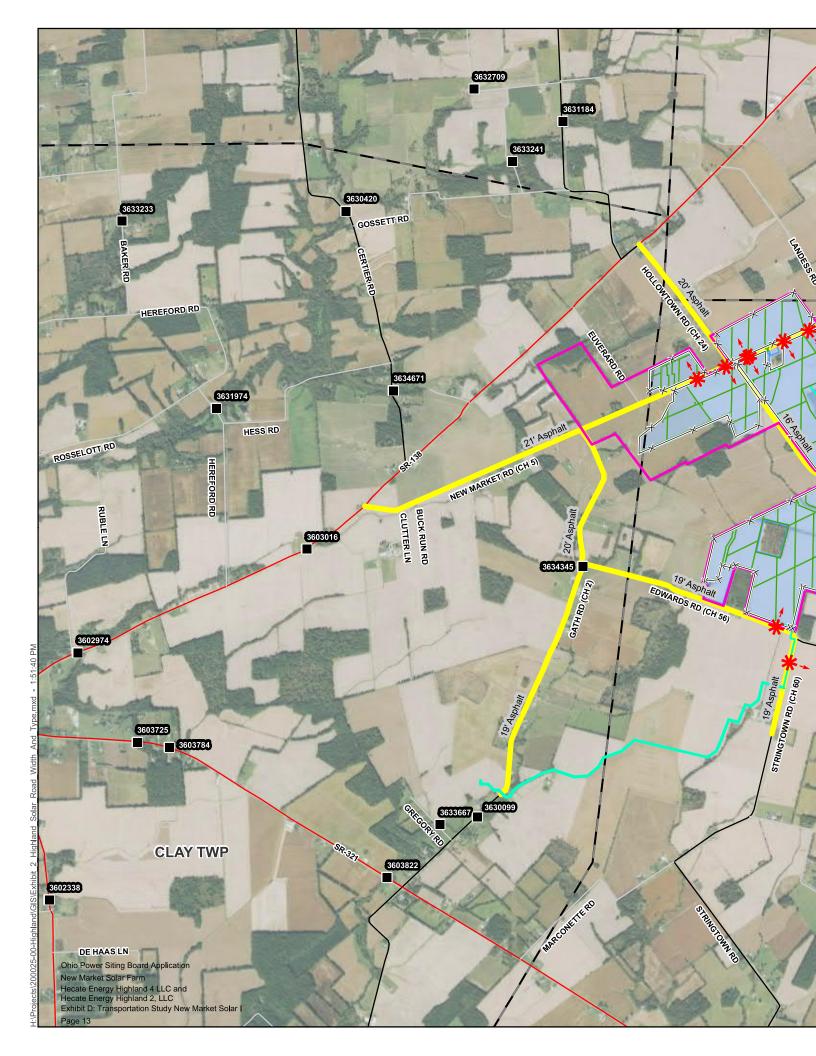

Although many of the eight (8) identified culverts appear to be structurally sound, there are two (2) locations that may require more thorough monitoring throughout construction. Both culverts, located along Hollowtown Road, have shallow cover and may need repair work done during/after construction. Each pipe should be analyzed to determine if necessary improvements are needed to accommodate the construction traffic. There is also one (1) additional deteriorating pavement area that was identified and marked on Exhibit 3 of Appendix A. This location should be monitored during hauling and construction activities to ensure no further pavement failure develops. If conditions do worsen, maintenance repairs may be required to fix the damaged roadway sections.

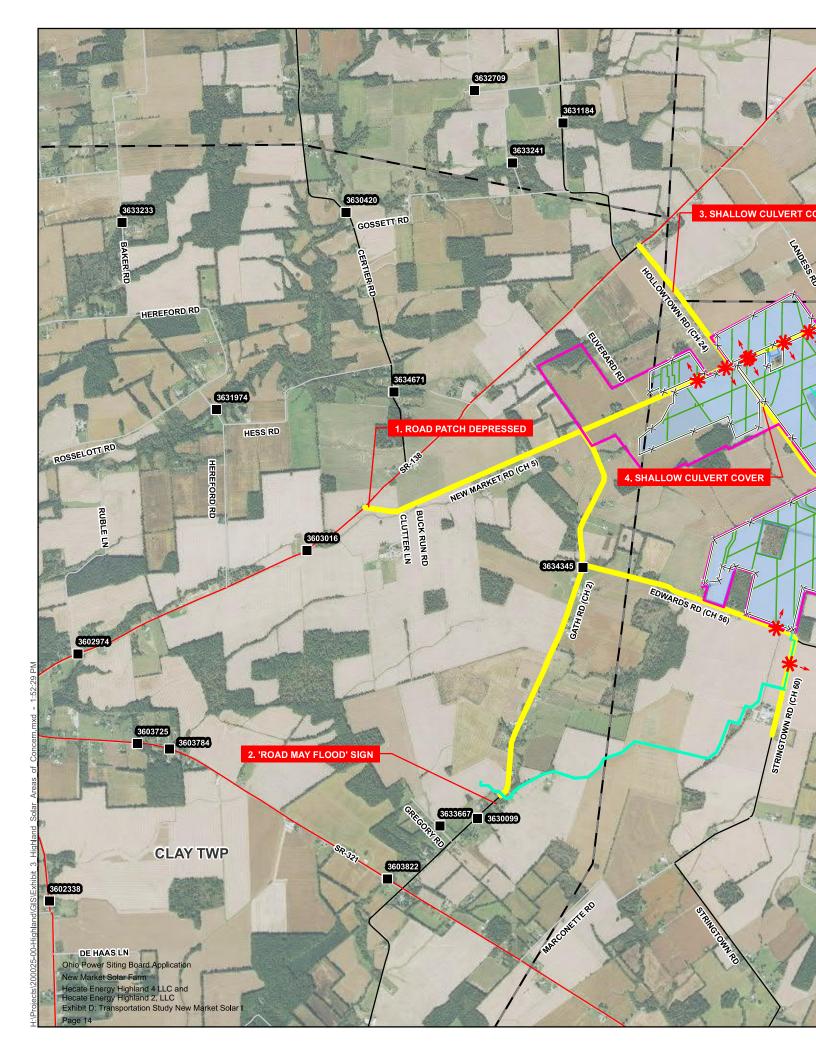

D. Special Hauling Requirements

Due to the size of the transformer required for the substation, an overweight/oversize permit may be necessary. However, the remainder of the construction vehicles for the project will be legal heights, widths, and weights, and would not require obtaining special hauling permits. All permits necessary to transport the transformer will be secured as necessary during final engineering and design.

Fatality Facts 2018 State by state

Overview

The number and types of motor vehicle crash deaths differ widely among the 50 states and the District of Columbia. A state's population has an obvious effect on the number of motor vehicle deaths. Fatality rates per capita and per vehicle miles traveled provide a way of examining motor vehicle deaths relative to the population and amount of driving. However, many factors can affect these rates, including types of vehicles driven, travel speeds, rates of licensure, state traffic laws, emergency care capabilities, weather, and topography.

The following facts are based on analysis of data from the U.S. Department of Transportation's (https://www-fars.nhtsa.dot.gov) Fatality Analysis Reporting System (FARS).

Posted December 2019.

Fatal crash totals

There were 33,654 fatal motor vehicle crashes in the United States in 2018 in which 36,560 deaths occurred. This resulted in 11.2 deaths per 100,000 people and 1.13 deaths per 100 million miles traveled. The fatality rate per 100,000 people ranged from 4.4 in the District of Columbia to 22.2 in Mississippi. The death rate per 100 million miles traveled ranged from 0.54 in Massachusetts to 1.83 in South Carolina. (#fn1)

Population, fatal motor vehicle crashes, motor vehicle crash deaths and motor vehicle crash death rates per state, 2018

Deaths by road user

In 2018, the types of motor vehicle crash deaths varied across states. For example, Wyoming had the highest percentage of deaths involving SUV and pickup occupants (49 percent) and a relatively low percentage of deaths involving car occupants (23 percent). In contrast, Vermont had the highest percentage of deaths involving car occupants (49 percent) and a relatively low percentage of deaths involving SUV and pickup occupants (26 percent). Hawaii reported relatively low proportions of fatalities for both cars (15 percent) and SUVs and pickups (15 percent), but a high percentage of motorcyclist deaths (29 percent) and the highest percentage of pedestrian deaths (36 percent). The District of Columbia had the highest percentage of crash deaths involving bicyclists (10 percent) and a high percentage involving pedestrians (35 percent) and motorcyclists (26 percent).

Alcohol involvement

Some states report blood alcohol concentration (BAC) for only a small percentage of passenger vehicle drivers. If BAC is missing for a driver, it is estimated by the U.S. Department of Transportation's multiple imputation model. However, BAC information is most precise in states that report a high percentage of crashes where BAC information is reported. In the following table, estimated percentages of fatally injured passenger vehicle drivers with BACs at or above 0.08 percent are shown only for states in which BAC reporting for fatally injured drivers was 70 percent or higher. Estimated percentages are based on known BAC when available and imputed BAC for the remaining drivers.

For the nation in 2018, BAC was reported for 65 percent of fatally injured passenger vehicle drivers. Reporting rates varied substantially, from a high of 100 percent (District of Columbia) to a low of 26 percent (Indiana).

Thirty-one states and the District of Columbia had BAC reporting rates of at least 70 percent. Among these states, Montana had the highest estimated percentage of fatally injured drivers with BACs of 0.08 percent or higher (45 percent) and West Virginia had the lowest (12 percent).

Estimated number and percent of fatally injured passenger vehicle drivers with BAC ≥ 0.08 percent by state, 2018

Page 30

Based on daytime observational surveys conducted by the states, the nationwide rate of seat belt use among front seat passenger vehicle occupants in 2018 was 90 percent. The state with the highest observed seat belt use for front seat occupants was Hawaii, at 98 percent, while the lowest was New Hampshire at 76 percent.3 (#fn3)

Rates of restraint use among fatally injured motor vehicle occupants will be lower than the overall observed restraint use rate because unrestrained occupants are more likely than restrained ones to be fatally injured in a crash. Restrained fatally injured occupants include occupants in child safety seats and occupants restrained by seat belts. In 2018, fatally injured occupants were approximately half as likely to have been restrained compared with the nationwide average. California had the highest restraint use percentage among fatally injured occupants at 61 percent. New Hampshire had the lowest restraint use among fatally injured occupants at just 28 percent.

Rural versus urban

Nationwide, 45 percent of motor vehicle crash deaths in 2018 occurred in rural areas. The states with the highest percentage of crash deaths on rural roads were South Dakota (90 percent), Vermont (88 percent), and North Dakota (87 percent). The states with the lowest percentage were New Jersey (8 percent) Massachusetts (10 percent), and Connecticut (13 percent). The District of Columbia had 0 crash deaths in rural areas because its entirety is coded as an urban area.

The Insurance Institute for Highway Safety (IIHS) is an independent, nonprofit scientific and educational organization dedicated to reducing the losses — deaths, injuries and property damage — from motor vehicle crashes.

The Highway Loss Data Institute (HLDI) shares and supports this mission through scientific studies of insurance data representing the human and economic losses resulting from the ownership and operation of different types of vehicles and by publishing insurance loss results by vehicle make and model.

Both organizations are wholly supported by these auto insurers and insurance associations (/about-us/member-groups).

APPENDIX D

Area of Concern 1- New Market Road

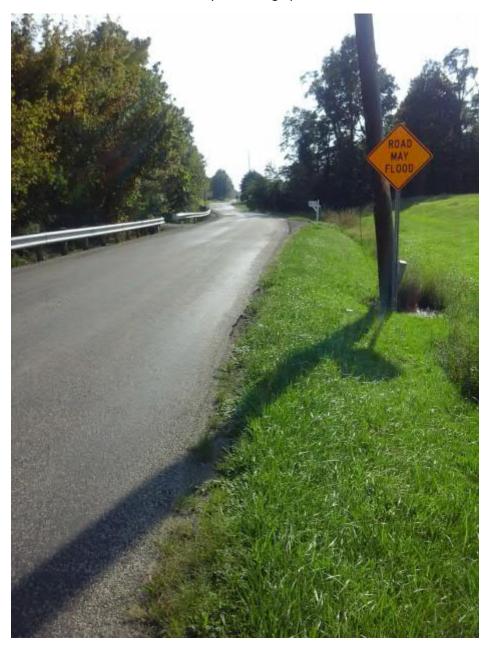

24 inch concrete patch depressed in road.

Area of Concern 2- Gath Road

"Road May Flood" sign present.

Area of Concern 3- Hollowtown Road

Shallow cover over existing elliptical concrete pipe.

Area of Concern 4- Hollowtown Road

Shallow cover over existing elliptical concrete pipe.

APPENDIX E

Highland Solar, Phase 2 65MW - Truck Load Estimation August-20

Solar Panel Truck Estimation

Solar Panels Assumed for Project 219284
Solar Panels/Truck 648

Trucks Needed for Solar Panel Delivery 338 trucks

Notes/Assumptions:

- 1. Panels are assumed to be 72-cell modules (JKM400M072L-V).
- 2. Number of solar panels taken from drawing HIGHLAND-GA-004

Gravel Truck Estimation

Trucks Needed for Gravel Delivery	3370 trucks
Total Gravel Volume of All Access Roads	40440 cy
Volume of Access Road Aggregate	1091870 cf
Depth of Aggregate for Access Road	0.5 ft
Width of Access Road	20 ft
Length of Access Road	109187 ft

Notes/Assumptions:

- 1. For consistency of calculations paved roads were assumed to use the same gravel section as stone roads.
- 2. Assumed 12 cy/truck for gravel delivery.

Other Facilities Truck Estimation

Length of Fencing 50143 ft Linear Feet per Truck 10000

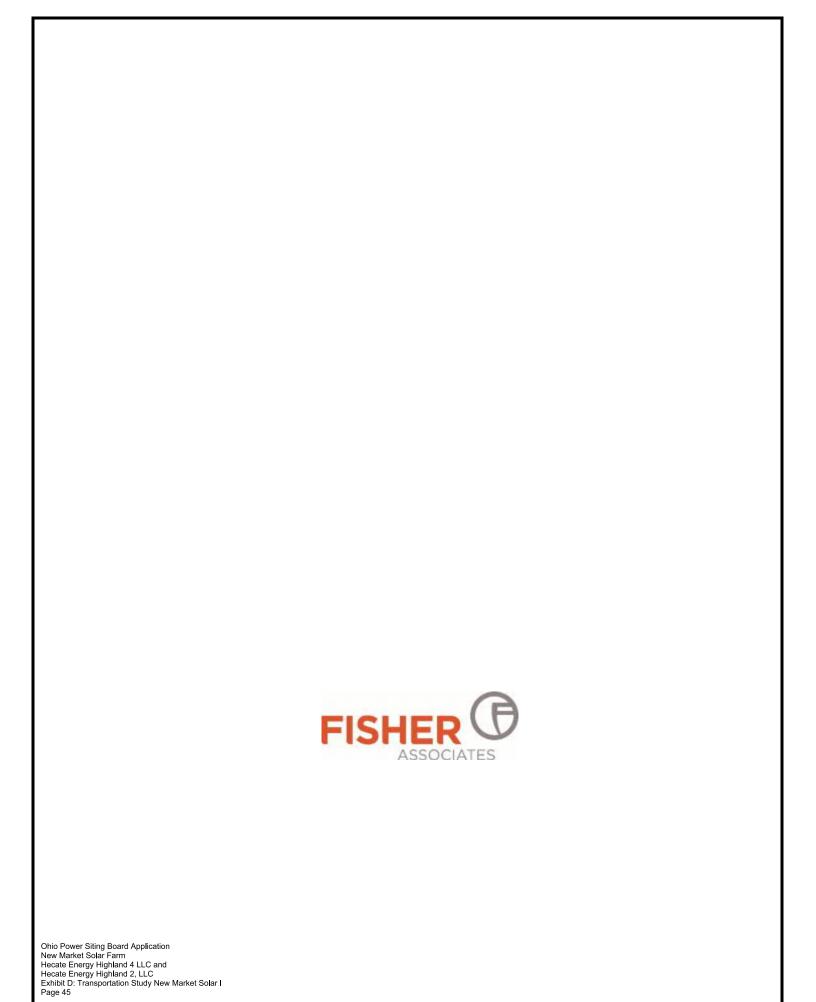

Trucks Needed for Fencing 8 trucks
Other Facilities 232 trucks

Notes/Assumptions:

- 1. Assuming three trucks will be necessary for posts and gates.
- 2. Number of trucks assumed for other facilities is based off of the assumption from other solar projects that solar panels make up 60% of non-aggregate/earthwork number of trucks needed for project.

Total Estimation of Trucks for Project 3948 trucks

DUE TO THE HIGH NUMBER OF ACCESS ROADS WE ESTIMATE THE HIGHLAND SOLAR, PHASE 2 65 MW PROJECT WILL HAVE BETWEEN 3,800 AND 4,200 TRUCKS FOR THE PROJECT, WITH THE VAST MAJORITY OF HAULING OCCURING DURING ACCESS ROAD CONSTRUCTION AND PAVING ACTIVITIES.
