Ms. Kim Wissman Chief, Power Siting Section Ohio Power Siting Board 180 East Broad Street Columbus, Ohio 43266-0573

Columbia Gas of Ohio, Inc.

Westlake High-Pressure Betterment Project

Case No. 94-1026-GA-BLN

Dear Ms. Wissman:

In accordance with the stipulation filed on September 22, 1994 in the above-referenced docket, Columbia Gas of Ohio, Inc. hereby submits its annual report summarizing the results of the 1996 monitoring survey of the wetland in Lorain County, Ohio. Six copies are attached, and it is my understanding that such number is sufficient for any necessary distribution.

Please contact me at 460-4666 if you have any questions.

Very truly yours,

Amy L. Koncelik

### 1.0 INTRODUCTION

### 1.1 PURPOSE

3D/Environmental (3D/E) was retained by Columbia Gas of Ohio (Columbia) to conduct wetland monitoring over a 5 year period starting in 1995. This ongoing survey involves monitoring a shrub/scrub wetland located in Lorain County, Ohio. (Prior to the start of the monitoring, 3D/E completed a wetland delineation of the area during a pipeline corridor survey conducted on May 12, 1994). The purpose of the monitoring has been to assess impacts to wetland vegetation, soils, and hydrology resulting from directional-drilling and open-cut construction techniques. This will also provide valuable scientific information. The methods used to collect, process and report data has been standardized in order to promote replication and allow for effective comparison over time.

The present report gives the results of the 1996 survey. In addition to providing the results of the second year sampling conducted on June 6, 1996, the report compares these results with those from the 1995 survey. The original scope of the monitoring consisted of sampling three 100 m transects, however, between the 1995 sampling and the 1996 sampling, the second transect was permanently altered by the installation of a sewer line. As a result, the 1996 survey, and future surveys only include data from two transects. The yearly results are being provided to Columbia for submittal to the Ohio Power Siting Board (OPSB).

### 1.2 BACKGROUND

During the initial wetland delineation conducted by 3D/E on May 12, 1994 this area was determined to be a wetland. Wetlands are defined as per the interagency cooperative publication entitled the *Federal Manual for Identifying and Delineating Jurisdictional Wetlands* (1987). This definition of wetlands in this manual reads as follows:

"Wetlands are those areas inundated or saturated by surface or ground water at a frequency and duration sufficient to support and that under normal circumstances do support-a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, and similar areas."

This definition identifies three essential characteristics possessed by wetlands: (1) hydrophytic vegetation; (2) hydric soils; and (3) wetland hydrology. In order to satisfy the definition of hydric vegetation, over 50 percent of the dominant species must have a wetland indicator status, as determined by the USFWS, of OBL, FAC or FACW. By definition, OBL species are found in wetlands >99 percent of the time, FACW species are located in wetlands between 67 and 99 percent of the time, and FAC species are found in wetlands between 33 and 66 percent of the time.

Soil is classified as hydric if it is saturated, flooded or ponded long enough during the growing season to develop anaerobic conditions in the upper surface. Wetland hydrology is met if an area which is inundated or saturated to the surface for at least five percent of the growing season in most years.

### 1.3 DESCRIPTION OF AREA

The wetland is located in northeastern Lorain County, Ohio just north of I-90 on the southwest corner of Chester Road and Lear Nagle Road (Figures 1 & 2). The area is located in the glaciated region of Ohio (Flint 1971, USDA 1976). During presettlement the northern portion of Lorain County was composed of a combination of Mixed Oak Forest, Mixed Mesophytic Forest, Beech Maple Forest, and Elm-Ash Swamp Forest depending on elevational level (Anderson 1993; Braun, 1950; Gordon 1966, 1969; Vankat 1979). The present wetland exists on the site of a vineyard which was abandoned approximately 30 years ago.

### 1.0 INTRODUCTION

### 1.1 PURPOSE

3D/Environmental (3D/E) was retained by Columbia Gas of Ohio (Columbia) to conduct wetland monitoring over a 5 year period starting in 1995. This ongoing survey involves monitoring a shrub/scrub wetland located in Lorain County, Ohio. (Prior to the start of the monitoring, 3D/E completed a wetland delineation of the area during a pipeline corridor survey conducted on May 12, 1994). The purpose of the monitoring has been to assess impacts to wetland vegetation, soils, and hydrology resulting from directional-drilling and open-cut construction techniques. As a result, the 1996 survey, and future surveys only include data from two transects. The yearly results are being provided to Columbia for submittal to the Ohio Power Siting Board (OPSB).

### 1.2 BACKGROUND

During the initial wetland delineation conducted by 3D/E on May 12, 1994 this area was determined to be a wetland. Wetlands are defined as per the interagency cooperative publication entitled the *Federal Manual for Identifying and Delineating Jurisdictional Wetlands* (1987). This definition of wetlands in this manual reads as follows:

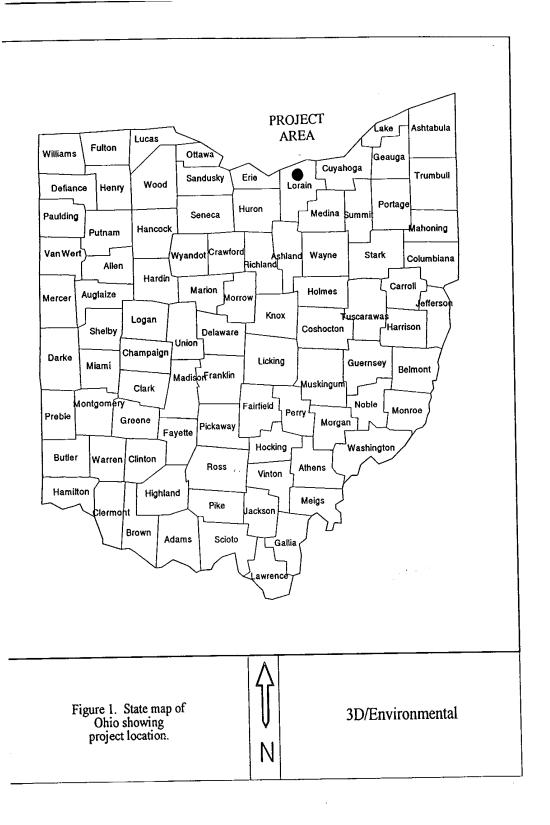

"Wetlands are those areas inundated or saturated by surface or ground water at a frequency and duration sufficient to support and that under normal circumstances do support-a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, and similar areas."

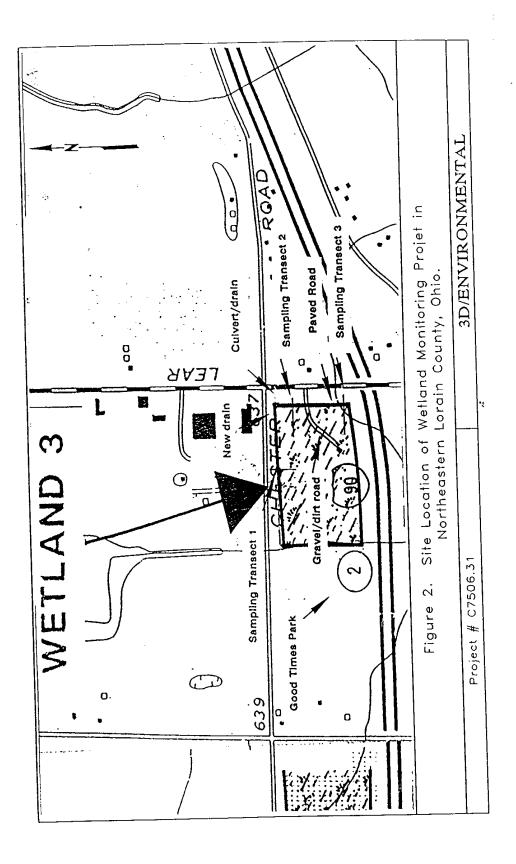

This definition identifies three essential characteristics possessed by wetlands: (1) hydrophytic vegetation; (2) hydric soils; and (3) wetland hydrology. In order to satisfy the definition of hydric vegetation, over 50 percent of the dominant species must have a wetland indicator status, as determined by the USFWS, of OBL, FAC or FACW. By definition, OBL species are found in wetlands >99 percent of the time, FACW species are located in wetlands between 67 and 99 percent of the time, and FAC species are found in wetlands between 33 and 66 percent of the time.

Soil is classified as hydric if it is saturated, flooded or ponded long enough during the growing season to develop anaerobic conditions in the upper surface. Wetland hydrology is met if an area which is inundated or saturated to the surface for at least five percent of the growing season in most years.

# 1.3 DESCRIPTION OF AREA

The wetland is located in northeastern Lorain County, Ohio just north of I-90 on the southwest corner of Chester Road and Lear Nagle Road (Figures 1 & 2). The area is located in the glaciated region of Ohio (Flint 1971, USDA 1976). During presettlement the northern portion of Lorain County was composed of a combination of Mixed Oak Forest, Mixed Mesophytic Forest, Beech Maple Forest, and Elm-Ash Swamp Forest depending on elevational level (Anderson 1993; Braun, 1950; Gordon 1966, 1969; Vankat 1979). The present wetland exists on the site of a vineyard which was abandoned approximately 30 years ago.

## 2.0 METHODS

## 2.1 VEGETATION SAMPLING

The objective of the vegetation monitoring is to: (1) identify the conditions of vegetation within the area of impact; (2) monitor changes in species composition over time (with particular emphasis on wetland species); and (3) monitor the invasion of exotic plants which could potentially impede the growth of wetland species. Vegetation was monitored qualitatively and quantitatively using both passive and active sampling methods as described below.

# 2.1.1 Active Sampling

Quantitative sampling was conducted using a modified line-intercept technique and nested-quadrat. The line-intercept technique was used to identify and record existing conditions and determine changes in the species complement and vigor of the canopy (i.e., trees and shrubs > 3 m tall). Transects crossing the pipeline were randomly selected and permanently-marked with rebar stakes. Species which intercepted the line were recorded along with their coverage. Permanent transects allow a direct measurement of vegetative change from year to year. In addition, three categories were used to determine the condition of trees and shrubs: (1) LIVE -- appears to be in relatively good condition, leaves are green, there is no wilting, or dieback; (2) STRESSED -- appears to be in poor condition, chlorotic leaves, wilting or leaf drop; and (3) APPARENTLY DEAD - no observable green foliage, the stem is dry and brittle with no live wood.

Nested-quadrats (3m², 1m² and 0.5m²) were used to identify and record existing conditions and determine changes in herbaceous species. Six nested-quadrats were randomly established along each of three transect which crossed the pipeline. However, following the 1995 survey a sewer line was put in and destroyed transect 2. As a result, the 1996 survey and future surveys, will consist of just 2 transects. The nested-quadrats were permanently-marked using rebar stakes. At each quadrat location, the frequency and percent cover of all species were recorded. Plants were identified using a variety of field manuals including: Fernald (1950), Gleason (1952abc), Fassett (1957), Braun (1961), Braun (1967), Radford et al. (1968), Weishaupt (1970), Hitchcock (1971), Voss (1972), Stuckey and Roberts (1977), Harlow et al. (1978), Barnes (1981), Lellinger (1985), Voss (1985), Weishaupt (1985), Case (1987), Fisher (1988), Burns and Honkala (1990), Gleason and Cronquist (1991), Brewer and Vankat (1992abc), Flora of North America editorial committee (1993), Homoya (1993), and Cooperrider (1994). Particular attention was given to native wetland species. The hydric status of individual species was based on its National Wetland Inventory Status (USFWS, 1988).

Numerous exotic (alien) plant species have established in northeastern Ohio. As alien plants invade natural areas, they compete with native species for resources, alter

microenvironments and plant community structure, and change patterns of succession (Bratton, 1982; Ebinger, 1983; Ebinger et al., 1984; Harty, 1987; Westman, 1990). During the monitoring, particular attention was given to *Rosa multiflora* (Appendix D). *Rosa multiflora* was introduced from eastern Asia for wildlife cover and food. It is a thorny shrub with a broad based stem system rather than an erect growth form, and may reach a height of 15 feet. *Rosa multiflora* invades prairies, savannas, open woodlands, pastures, and forest edges and forms dense, impenetrable thickets which smothers native vegetation. Seeds can remain viable for one to two decades. *Rosa multiflora* can also propagate by layering (where tips of branches touch the ground and form roots) or by shallow root sprouting (Szafoni, 1990).

# 2.1.2 Passive Sampling (Photomonitoring)

Photographs were taken at three points corresponding to the transects at the time of active vegetation sampling. These photographs provide a permanent ground-level record of physical changes in the wetland as it exists during the field survey. Although this method does not provide detailed information, it does provide time-based illustrations of vegetative growth, composition and the interspersion of vegetative communities.

## 2.2 SOILS

Soil monitoring consisted of collecting soil cores within the nested plots and recording the physical conditions of the soil. Information on soils was gathered in order to determine if characteristics of hydric soils are altered by pipeline construction. Munsell Soil Color Charts (1975) were used to identify the hue, value and chroma of each soil sample. An overview of soil characteristics was provided by the soil survey of Lorain County (USDA, 1976).

### 2.3 HYDROLOGY

Hydrologic parameters important to wetlands include: precipitation (frequency and duration), depth of flooding, and a seasonal high ground water. Surface-water levels were determined and reordered at locations corresponding to the soil sample. If surface water was not present, the depth to free-standing water in soil cores or the depth to soil saturation was recorded. The soil survey of Lorain County (1976) was used determine hydrological factors.

### 3.0 RESULTS

## 3.1 VEGETATION

## 3.1.1 Active Sampling

Five species of shrubs were found along the line transects producing a total of 83.5 percent cover (Table 1, Appendix A and B). Viburnum recognitum was the most abundant shrub with 51.0 percent cover followed by Rhamnus alnifolia (22.5 percent), and Ulmus americana and Cornus racemosa (each with 3.5 percent), and Salix sp. (3.0 percent). Of the six shrub species in the line transects, one was Obligate (OBL), two were Facultative Wetland (FACW), and two had not been given indicator status by (USFWS, 1988). A total of 77.7 percent of the species were OBL, FACW or FACW. The shrub layer satisfies the vegetation criteria as defined by the USCOE for a wetland since over 50.0 percent of the species were OBL, FACW or FAC.

Table 1. Average percent cover for shrubs (1-3 meters) from both transects.

Species	Percent	Indicator Status
	51.0%	FACW
Viburnum recognitum Rhamnus alnifolia	22.5%	OBL
Ulmus americana	3.5%	FACW -
Cornus racemosa	3.5%	-
Salix sp.	3.0%	-
Total	83.5%	

Two trees species were found along the line transects for a total of 53.5 percent cover (Table 2). *Ulmus americana* was the most abundant with 46.0 percent and *Acer rubrum* had 7.5 percent. Since both species (100 percent) are considered wetland species (one FACW and one FAC), the vegetation criteria for a wetland was satisfied.

Fifty-two species of plants were found in the nested herbaceous quadrats. The  $0.5 \, \text{m}^2$  quadrats had 33 species, the  $1.0 \, \text{m}^2$  quadrats had 38 species, and the  $3.0 \, \text{m}^2$  quadrats had 52 species. The plant species and the average percent cover for  $3.0 \, \text{m}^2$  are shown in Table 3. The plant species and their percent cover for the  $0.5 \, \text{m}^2$  quadrats and  $1.0 \, \text{m}^2$  quadrats are given in Appendix A, along with all the data for the nested quadrats.

Table 2. Average percent cover for trees (>3 meters) from both transects.

Species	Percent	Indicator Status
Ulmus americana Acer rubrum	46.0% 7.5%	FACW FAC
Total	53.5%	

The most abundant species in the 3.0 m² quadrats was Viburnum recognitum with 22.4 percent, followed by Lysmachia nummaralia (12.1 percent), Rhamnus alnifolia (9.9 percent), Juncus tenius (7.0 percent), Juncus effusus (4.2 percent), Bidens sp. (3.3 percent) Polygonum sp. (2.8 percent), Solidago canadensis (2.6 percent), Prunella vulgaris (2.0 percent), Medicago saiva (1.9 percent), Typha latifolia (1.3 percent), Cornus racemosa (1.2), Euthamia graminifolia (1.2 percent), Rumex crispus (1.2 percent), and Geum laciniatum (1.0 percent. All other species had less than 1.0 percent cover.

Of the fifty two species in the 3.0 m<sup>2</sup> quadrats fourteen were Facultative Upland (FACU), eight Facultative (FAC), six Facultative Wetland (FACW), and seven Obligate (OBL) (USFWS, 1988). No Obligate Upland (UPL) were found in the quadrats. Seventeen species did not have a status because they could not be identified to the species level, or they simply had not been given an indicator status by the U.S. Fish and Wildlife Service (USFWS, 1988). Some taxa could not be identified to species because of the lack of flowers or other parts, but may be determined to species during the subsequent sampling. A total of 67.5% of the species were OBL, FACW, or FAC. Since over 50.0% of the species were OBL, FACW, or FAC the wetland satisfies the herbaceous vegetation criteria for a wetland.

The average percent frequency for  $3.0\text{m}^2$  quadrats are given in Table 4. The average percent frequency for the  $0.5\text{m}^2$  quadrats and  $1.0\text{ m}^2$  are given in Appendix A and B. Viburnum recognitum was the most frequently occurring species in the  $3.0\text{ m}^2$  quadrats (83.0 percent), followed by Geum lacinatium (75.0 percent), Rhamnus alnifolia (67 percent), Lycopus americanus (50 percent, Lysmachia nummalaria (50 percent), Polygonum sp. (41.7 percent), Prunella vulgaris(41.7 percent), Solidago canadensis (41.7 percent), and Valerianella sp. (41.7 percent). All other species had an average percent frequency of less than 40.0 percent.

# 3.1.1.1 Present Condition of Shrubs and Trees

The number and condition of the shrub and tree stems found along the transects is shown in Tables 5 and 6. There were a total of 72 stems of shrubs. Viburnum recognitum

had the greatest number of stems with 52, followed by *Ulmus americana* with 15. Three of the 72 stems (4.2 percent) were dead. All the dead stems were *Viburnum recognitum*. Of the 72 stems of shrubs 69 (95.8%) were live. No stems appeared to be stressed.

For tree species, a total of 29 stems were located within the transects. *Ulmus americana* was the densest with 27, followed by *Acer rubrum* with 2 stems. Of the 29 stems, 23 (79.3 percent) were live and 6 (20.7 percent) dead. No stems were classified as stressed.

21	-	6	27
2	-	-	2
23	0	6	29
	21 2	21 - 2 - 	21 - 6 2

# 3.1.1.2 Exotic Plant Species

No exotic trees or shrubs were found along the transects. Ten species of plants in the herbaceous layer are considered to be exotic (non-native) producing a total percent cover of 17.3 percent. Lysimachia nummularia had the greatest percent cover with 12.8 percent, followed by Medicago sativa (1.8 percent). The remaining exotic species all had percent cover values less than 1.0 percent. The exotic species with the greatest percent frequency was Lysimachia nummularia with 50.0 percent. The remaining seven exotic species all had a frequency of less than 40.0 percent.

# 3.1.2 Passive Sampling

Photographs were taken at three points corresponding to the line transects and are provided in Appendix C & D. These photographs provide a permanent ground-level record of physical changes in the wetlands. Although this method does not provide detailed information, it does provide time-based illustrations of vegetative growth and composition and the interspersion of vegetative communities. The 1996 photographs, along with the vegetative sampling, were taken at the same time of the year as they were in 1995 in order to produce adequate comparisons between years. In comparing the photographs there were no significant changes in vegetation between 1995 and 1996.

### 3.2 SOIL SAMPLING

The wetland in which the vegetation sampling was conducted is composed primarily of Miner silty clay loam which is a hydric soil (3D/Environmental, 1994, USDA, 1976). All soil samples taken in the nested quadrats had a low chroma matrix and mottles, which qualify them as hydric. The soil color for all soil samples are given in Table 7. The soil colors had not changed significantly since the 1995 survey.

## 3.3 SOIL HYDROLOGY

All 12 soil samples were saturated in the upper 12 inches of the soil profile (Table 7). Given the fact that the wetland was saturated on 6 June 96 it is very likely that it had been saturated for at least two weeks during the growing season, which qualifies it as having soil hydrology. Stained leaves located at various locations in the wetland also indicate that the wetland has soil hydrology.

Table 7. Soil matrix and mottle colors for 12 soil samples taken from nested-quadrats located in the 2 transects as well as depth to soil saturation.

Sample	Matrix Color	Mottle Color	Saturation Depth
Transect #1	<del></del>		
Sample #1	10YR 5/1	10YR 6/8	10"
Sample #2	10YR 5/1	10YR 4/4	10"
Sample #3	10YR 5/1	10YR 5/6	10"
Sample #4	10YR 4/1	10YR 6/6	10"
Sample #5	10YR 4/1	10YR 4/4	10"
Sample #6	10YR 4/1	10YR 4/4	10"
Transect #3			
Sample #13	10YR 5/1	10YR 5/8	inundated
Sample #14	10YR 4/1	10YR 6/6	not saturated
Sample #15	10YR 4/1	10YR 5/8	not saturated
Sample #16	10YR 5/1	10YR 6/6	10"
Sample #17	10YR 5/1	10YR 6/6	10"
Sample #18	10YR 4/1	10YR 4/6	10"

## 4.0 CONCLUSION

Because over 50% of species in the tree, shrub, and herbaceous layers in the 1996 survey were either Facultative (FAC), Facultative Wetland (FACW), or Obligate (OBL), the vegetation criteria to categorize this area as a wetland were satisfied. Likewise, the criteria for soils, and hydrology were also met. As a result, the study area is still considered a wetland as of 6 June 1996. Comparing photographs taken of the wetland during the preliminary survey conducted on 4 May 1994 (3D/Environmental,1994), and the 1995 monitoring survey with the present 1996 survey there appears to be no real difference in the wetland before and after the directional boring. Based on the composition of trees, shrubs, and herbs in the three transects and nested-quadrats this wetland continues to be very similar in composition to other early successional wetlands in this part of the state (Anderson 1993).

The evaluation of the condition of the shrubs and trees showed that only 4.2% of the shrubs and 20.7% of the trees were stressed or dead. In addition, of the dead trees (20.7%) were American elms that had been infected by Dutch elm disease. As a result, the death of American elms during the 1996 survey, or future surveys, can not be attributed to the construction of pipeline. Also, a ditch going into the northeast end of the wetland has been constructed by the owner of the wetland in an attempt to drain it. If the wetland is successfully drained it may cause the death of trees, shrubs, and herbs resulting in a change in composition and structure from a wetland plant community to an upland plant community; a change in the wetland that may have very little to do with the directional-drilling and open-cut construction techniques that are being monitored in this study. In addition, during the spring of 1996 the ditch that parallels Chester Road has been enlarged, which may also contribute to the draining of the wetland.

No exotic species of trees or shrubs were found in the two transects. Although no exotics were found in the shrub layer Rosa multiflora is found in other parts of the wetland and if this species increases significantly the wetland may be converted to upland. Ten species of plants in the herbaceous layer are considered to be exotic (non-native) producing a total percent cover of 17.3 percent. Lysimachia nummularia had the greatest percent cover with 12.8 percent, followed by Medicago sativa (1.8 percent). The remaining exotic species all had percent cover values less than 1.0 percent. Since the dominant exotic herbs are not considered aggressive invaders they will probably not be a problem with regard to replacing wetland plants at this site.

APPENDIX B: VASCULARPLANT SPECIES OBSERVED WITHIN THE NESTED-QUADRATS AND THREE TRANSECTS ESTABLISHED IN THE WETLAND IN LORAIN COUNTY AS WELL AS REPRESENTATIVE ILLUSTRATIONS

Vascular plant species observed within the nested-quadrats and three transects established in the wetland in Lorain County.

Species

Common Name

ACERACEAE

Acer rubrum L.

Red maple

ALISMATACEAE

Alisima subcordatum Raf.

Water plantain

ANACARDIACEAE

Toxicodendron radicans (L.) Kuntze

Poison ivy

APIACEAE

Daucus carota L.

Queen Anne's lace

APOCYNACEAE

Apocynum cannabinum L.

Indian hemp

ASCLEPIADACEAE

Asclepias incarnata L.

Swamp milkweed

ASTERACEAE

Achillea millefolium L. Ambrosia artemisifolia L.

Aster sp. Bidens sp.

Cirsium discolor (Muhl.) Spreng.

Cirsium sp.

Erigeron philadelphicus L.

Erigeron sp.

Eupatorium perfoliatum L.

Euthamia graminifolia (L.) Nutt.

Solidago canadensis L.

Solidago sp.

Taraxacum officinale Weber

Tussilago farfara L.

Yarrow

Annual ragweed

Aster Tickseed Field thistle

Thistle Dasiy fleabane

Fleabane Boneset

Flat-top golderod Canada goldenrod

Goldenrod

Common dandelion

Coltsfoot

BALSAMINANACEAE

Impatiens sp

Touch-me-not

BRASSICACEAE

Brassica nigra L.

Black mustard

CAPRIFOLIACEAE

Viburnum recognitum Fern.

Arrow-wood

CHENOPODIACEAE

Chenopodium album L.

Lamb's quarters

Vascular plant species observedwithin the nested-quadrats and three transects established in the wetland in Lorain County.

Species

Common Name

CLUSIACEAE

Hypericum sp.

st. John's-wort

CORNACEAE

Cornus amomum Mill. Cornus stolonifera Michx. Silky dogwood Red osier dogwood

CYPERACEAE

Carex lacustris Willd. Carex vulpinoidea Michx. Carex sp. Scirpus atrovirens Muhl. Sedge Fox sedge Sedge Bulrush

DIPSACACEAE

Dipsacus sylvestris Huds.

Teasel

FABACEAE

Lathyrus sp.
Medicago lupulina L.
Medicago sativa L.
Trifolium pratense L.
Trifolium repens L.
Vicia sp.

Vetchling Black medick Alfalfa Red clover White clover Vetch

FAGACEAE

Quercus sp.

Oak

GUTTIFURAE

Hypericum punctatum (Lam.)

Dotted St. John's-wort

JUNCACEAE

Juncus effusus L. Juncus tenius Willd. Juncus sp. Jointed rush Path rush Rush

LAMIACEAE

Lycopus americanus Muhl. Prunella vulgaris L. Water horehound Heal-all

ONOCLEACEAE

Onoclea sensibilis L.

Sensitive fern

OXALIDACEAE

oxalis sp.

Wood Sorrel

Vascular plant species observedwithin the nested-quadrats and three transects established in the wetland in Lorain County.

Species

Common Name

POACEAE

Muhlenbergia sp. Poa compressa L. Poa pratensis L. Muhly Canada bluegrass Kentucky bluegrass

POLYGONACEAE

Polygonum sp. Rumex acetocella L. Rumex crispus L. Smartweed Red sorrel Curled dock

PRIMULACEAE

Lysimachia nummularia L.

Marsh seedbox

RHAMNACEAE

Rhamnus alnifolia L'Her.

Alder buckthorn

ROSACEAE

Agrimonia parviflora Ait.
Agrimonia sp.
Cratagus sp.
Fragaria virginia Duchesne.
Geum laciniatum Murray
Potentilla simplex Michx.
Prunus serotina Ehrh.
Rosa multiflora Thunb. ex Murr.
Rubus allegheniensis T. Porter
Rubus flagallaris Willd.
Rubus sp.

Small-flowered agrimony
Agrimony
Hawthorn
Wild strawberry
Rough avens
Common cinquefoil
Black cherry
Multiflora rose
Blackberry
Dewberry
Blackberry

SALICACEAE

Salix nigra L. Salix sp. Black willow Willow

TYPHACEAE

Typha latifolia L.

Common cattail

ULMACEAE

Ulmus americana L.

American elm

VALERIANACEAE

Valerianella sp.

Corn salad

VITACEAE

Parthenocissus quinquefolia (L.) Planch. Parthenocissus sp. Vitis riparia Michx. Virginia creeper Virginia creeper River grape APPENDIX C: PHOTOGRAPHS OF THE THREE TRANSECTS IN THE WETLAND

Figure 1. Photograph on the left shows Transect #1 taken from Chester Road in 1995, while the photograph on the right shows Transect #1 in 1996.

Figure 2. Photograph shows the location of the former Transect #2 which was destroyed by the new sewer line.

Figure 3. Photograph on the top shows Transect #3 taken from Lear Road in 1995, while the photograph on the bottom shows Transect #3 in 1996. (Because the vegetation had grown up along the Lear Road the 1996 photo was taken from a slightly different angle.)

Figure 1. Photograph showing the enlarged ditch along Chester Road which could add to the draining of the wetland.

Figure 2 Photograph of man-made drainage ditch going into the wetland.

Figure 3. Two photographs of the wetland taken from different locations along Chester Road.
